The counties of Wicklow and Wexford contain an industrious and thriving population; and because industrious, the people are able to pay, from soils not superior to those of other districts, rents which would be intolerable in other parts of Ireland. The Wicklow peasantry are reckoned the finest in the world, and are proverbial for their handsome features and fine Roman profiles, and still more so as being a respectful, quiet, and well-conducted people. The county of Meath is remarkably fertile; but being less subdivided, is therefore less populous than any other part of Ireland, considering the richness of its soil. The same prosperity as that in Wicklow and Wexford, though perhaps in a smaller degree, prevails in Kildare, Carlow, and the Queen's County. One of the chief causes of this prosperity is, that a large portion of the population receive money payments for their daily labour, and another, that the *cottier* and *con* or *corn-acre* systems are here less resorted to. The wages of Leinster are usually 1s. a day in summer, and in winter from 8d. to 10d., without diet. The average rent for arable land is from £1 to £1, 10s., and for pasture land from £2 to £3 per acre. The general diet of the peasantry is potatoes, milk, strabout, eggs, butter, bacon, and herrings. Their dwellings are confessedly superior to those of Munster or Connaught. The resident gentry are more numerous, and take a great interest in the wellbeing of their tenantry. Leinster, therefore, may altogether be pronounced a much improved part of the country.

As the woollen and silk manufactures are still carried on in Dublin and other parts of Leinster, a slight sketch of their history may not be out of place in the account of that province. So early as the reign of Henry III. Irish woollen manufactures were imported from Ireland to England, duty free; and so excellent was their quality, that, from 1327 to 1357, they were exported to Italy, at a time when the woollen fabrics of the latter country had attained a high degree of

excellence. The prosperity of the trade is noticed in an act of Elizabeth; and so flourishing was it in the time of Sir William Temple, that he became apprehensive lest it should interfere with that of the English. In 1688, the woollen manufacture was established to a considerable extent in the liberties of Dublin. But this prosperity was soon interrupted by the English presenting a petition for the imposition of such heavy duties on the exportation of wool, as greatly injured the trade. It never, however, became extinct in the liberties, though it now extends only to the manufacture of coarse fabrics. In 1773, the Dublin Society, anxious for its revival, procured an order that the army should be clothed with Irish cloth. This employment, however, became soon monopolised by one or two great houses which had parliamentary interest: one of these failed in 1810, and the failure was followed by the bankruptcy of almost the entire woollen trade of Dublin; for the general credit was so much affected, that the banks refused to discount the bills of the manufacturers, and consequently the crash became general. The trade is now almost confined to the city of Dublin and its environs, where good hearth-rugs and carpeting are still manufactured.

The silk trade was introduced by the French refugees, and about 1693 fully established by them in the liberties of Dublin. In 1774 an act was passed, placing it under the direction of the Dublin Society, for the extent of two miles and a-half round the castle; and that society was empowered to make regulations for its management, which it accordingly did, and also opened a silk warehouse, and paid a premium of 5 per cent. on all sales made therein. But this warehouse was ruined by an act passed about the year 1786, prohibiting any of the funds of the Dublin Society from being applied to support any house selling Irish goods either wholesale or retail. This act gave to the manufacture a check by which hundreds of people were thrown out of employment. According to a return made in 1809, there were still 3760 hands engaged in it, who, after the passing of this cruel act, struggled to support the trade; but when the protecting duties were taken off in 1821, and steam communication opened with England, the Irish market was inundated with goods at a smaller price than that at which her native fabric could be produced, and thus the ruin of the trade was completed. The tawny fabric of silk and worsted (See No. 22), for which Dublin has long been famous, is the only branch of the silk business which has not materially suffered from these discouragements.

#### Chief Towns.

The chief towns in Leinster are *Dublin*, *Kilkenny*, *Drogheda*, *Wexford*, *Maryborough*, *Mullingar*, *Carlow*, *Birr*, or *Parsonstown*, and *Trim*.

*Dublin*, the principal town in Leinster, and the capital of Ireland, is situated at the margin of a beautiful bay, on a generally flat piece of country, through which flows the River Liffey, and is therefore agreeably placed both for commerce and the accommodation of a large population. In point of size, Dublin occupies a place between Edinburgh and London, and its appearance never fails to surprise and delight the stranger. In external aspect it is essentially an English town, being built of brick in a neat and regular manner, but abounding in a class of elegant public structures of stone, which resemble the more substantial embellishments of Paris and other continental cities. The river, flowing from west to east, divides the city into two nearly equal portions, and is a striking feature in the general plan. The leading thoroughfares of the city are easily comprehended. First, from east to west, there is the double line of houses and quays bordering upon the river, the lower part of which forms a harbour, and is crowded with vessels. Crossing this line at right angles, is the great line formed by Sackville, Westmoreland, and Grafton Streets, the first and second of which are connected by Carlisle Bridge, the lowest in a range of eight or nine which

## IRELAND.

the river at various distances from each other. All the quays, on the south side of the river, is a shorter arterial line of great importance, led by College Green, Dame Street, Castle Street, Thomas Street, being terminated to the east by the wings of the University. Though the ancient part of the city occupies the south bank of the river, there is a more modern and elegant on both sides; the squares and squares of the wealthy being here, contrary to the usual rule, in the north-east and south-east divisions. All the great lines are formed by houses of elegant proportions, chiefly devoted to commerce and perhaps no city can present a more complete series of shops and warehouses. Sackville Street, 100 paces in length and 6 in width, with a monumental pillar in the centre, and some of the finest public buildings in the world lending it their effect, must impress every one as something worthy of a great city. The spaciousness of several of the squares in the aristocratic districts is equally impressive. Merrion Square is half, and St Stephen's Green nearly a whole mile, in circumference; the latter containing seventeen acres of pleasure-ground in the centre.

On first walking into the streets of Dublin, the stranger is apt to see, in the throng of carriages and foot-passengers, nothing more than what he expects to find in all large cities. He soon observes, however, that, besides the luxurious class who occupy the better kind of vehicles, and the busy, well-dressed crowd who move along the foot-ways, there is a great multitude of mean and mendicant figures, such as are only to be found in a small proportion in other cities. This is the very first peculiar feature which the stranger detects in Dublin, and it is an unfortunate one. It is explained when we learn, that of the large population of Dublin—supposed to approach 300,000—fully three-fourths are beneath what is recognised in Britain as the middle rank. Thus the most respectable streets in Dublin, and the most elegant figures which appear in them, seem isolated in the midst of penury and meanness.

The public buildings of Dublin boast an elegance much above what might be expected from the general character of the city. In sailing up the river, the eye is first attracted by the Customhouse, a large and splendid edifice in the well-known taste of the Adams, surmounted by a dome, and very happily situated upon the north quay. The Post-Office, in Sackville Street, is in that graver form of the Grecian style which has more recently come into favour, extending above 200 feet in front, with a noble portico surmounted by a pediment. The simultaneous starting of the mail-coaches, at a certain hour every evening, from the court of this building, is one of the sights of Dublin. Opposite to it is a pillar in honour of Nelson, surmounted by a figure of that hero. At the upper extremity of Sackville Street is the Lying-in Hospital, a beautiful building, with which is closely connected the more celebrated Rotunda, together with an extensive plot of ornamental ground. The Four Courts—also a most superb structure—overlooks the river at a point considerably removed to the west, and completes the list of remarkable buildings in the northern division of the city. To the south of the river, the objects worthy of especial notice are more numerous. The buildings of the University (founded by Queen Elizabeth in 1592) occupy a conspicuous situation on the great transverse line of streets which has already been mentioned. Beneath an elegant Grecian front, 300 feet in length, an archway gives admission to a succession of spacious squares, chiefly composed of brick domestic buildings, and containing a theatre for examinations, a museum, a chapel, a refectory, a library, and other apartments necessary for the business of the institution. In the museum is preserved an ancient harp, generally represented as that of Brian Boromhe, a famous Irish king of the tenth century. There are usually about two thousand students in attendance at the University. Divided from this building only by the breadth of a street, is the Bank of Ireland, formerly

the place of assembly of the Irish Houses of Parliament. The deep colonnaded front of this building is one of the most beautiful pieces of architecture, not only in the British dominions, but in the world: it carries a charm like a fine picture. The hall where once the Commons of Ireland assembled—where the eloquence of a Grattan, a Curran, and a Flood, was once heard—is now altered to suit the purposes of a telling-room; but the House of Peers remains exactly as it was left by that assembly, being only occasionally used for meetings of the Bank directorate. The latter is a small, but handsome hall, adorned with tapestry representing transactions in the subjugation of Ireland by King William—the Battle of the Boyne, the Breaking of the Boom, and so forth, as also a few appropriate inscriptions.

In Kildare Street, at no great distance from the College and Bank, the halls of the Royal Society of Dublin present a powerful claim to the attention of strangers, in the great variety of curiosities, pictures, and models with which they are filled. In a perambulation of the city, the Castle is the next object worthy of notice. This ancient seat of the viceregal government, to which rumours of plots and insurrections have been so often brought by terror-struck spies or remorseful participators, is placed on slightly-elevated ground, in the midst of the old or southern division of the city. It consists of two courts, containing certain public offices, and the apartments of state used by the Lord-Lieutenant. In the lower court is the Castle Chapel, a beautifully-constructed and beautifully-furnished modern Gothic place of worship, the whole materials of which are of Irish production, and which cost above £40,000. The service performed here every Sunday forenoon, graced, as it is, by the finest vocal and instrumental music, while a rich 'religious light' streams through stained windows, and is reflected from the gorgeous stalls of civil and ecclesiastical dignitaries, is one of the most attractive things in Dublin. The state-apartments of the Viceroy are in the taste of the middle of the last century, and are elegant, but not remarkable for grandeur. In one is a bust of Chesterfield, who was Lord-Lieutenant in 1745. The most remarkable room is the ball-room, denominated St Patrick's Hall, which is spacious and lofty, and among other attractions, has a ceiling ornamented with pictures, emblematical of transactions in the history of Ireland.

In Ireland, old ecclesiastical structures are usually more curious for their antiquity than their beauty. Accordingly, the exterior of St Patrick's and Christ-Church, the two cathedrals of Dublin, is apt to appear ungainly to an eye fresh from Westminster or Melrose. In the former building, nevertheless, the interior of the choir in which service is usually performed, will impress every mind by its lofty proportions, its pompous monuments, and the dark stalls and niches, surmounted with the helmets and banners of the knights of the order of St Patrick. In visiting this ancient church, the predominant thought is—SWIFT. We look for his dwelling as we approach, and for his tomb when we enter—such is the power which genius has of fixing the feelings of men for all time upon every external thing connected with it! The deanery still exists in St Kevin Street, containing the portrait of Swift from which all the engraved likenesses have been derived. The streets immediately surrounding St Patrick's Cathedral are the meanest and vilest in the city. The houses have a ruinous and forlorn look, and the pavements are crowded with a population of the most wretched order. These streets are filled with shops, but the trades to which they are devoted serve rather to betray the misery than to manifest the comfort of the people. Here dealers in old clothes, pawnbrokers, spirit-dealers, and persons trading in offals, almost the only kinds of animal food indulged in by the lower orders of the people, abound.

At the western extremity of Dublin, on the north side of the river, is the celebrated public promenade denominated the Phoenix Park, said to consist of about

a thousand acres. Not only does this park greatly exceed those of London in extent, but it is questionable if even the Regent's Park, after all the expense incurred in ornamenting it, will ever match this domain in beauty. The ground is of an undulating character, and is covered with groups of fine old timber and shrubbery, amidst which are the domestic residences of the Lord-Lieutenant and his principal officers, besides some other public buildings, and a tall obelisk in honour of the Duke of Wellington's victories. A zoological garden has lately been added to the other attractions of the park.

Dublin was formerly a busy literary mart, in consequence of the state of the copyright law, which allowed of cheap reprints of British books being here issued. After a long interval, the activity of its publishers has lately revived, and there are now several houses which afford considerable encouragement to native talent. Dublin possesses a number of charitable institutions, conducted on a scale of great liberality; also several religious and educational societies, whose operations are extended over the whole kingdom. The trade carried on in the town refers chiefly to home consumption; and excepting tabinets or poplins, it is not distinguished as the seat of any manufacture. There is very little foreign export from Dublin. Its principal imports are—timber from the Baltic; tallow, hemp, and tar from Russia; wine and fruits from France, Spain, and Portugal; tobacco, bark, and spices from Holland; and sugar from the West India islands.

The most important branch of its commerce is that carried on with England, chiefly in connection with Liverpool, to whose market there are now large exports of native produce. Though the Liffey forms the harbour of the port, vessels of large burthen, and steam-boats, have an opportunity of preferring the harbour at Kingston (formerly called Dunleary), at the mouth of the bay, on its southern side. This harbour, which is constructed on a magnificent scale, with the neat town adjacent, may at all times be readily reached by railway from Dublin, which proves a great convenience to the inhabitants. At the opposite side of the bay from Kingston is Howth, whose celebrated 'hill' forms a distinguishing land-mark. In 1845 there were 260 sailing vessels under, and 218 above, 50 tons burthen, making an aggregate tonnage of 28,500; 35 steamers, with an aggregate burthen of 8650 tons; and the customs' receipts exceeded £1,043,000.

The number of light private vehicles in Dublin is one of its most remarkable distinctive features. These are generally of the kind called cars, drawn by one horse, and having a seat on each side, admitting of two or more persons sitting with their faces outwards. To keep a car is one of the highest aims of the ambition of a Dublin tradesman. 'Previous to the Union,' says an intelligent writer, who has been consulted with advantage, 'Dublin was the constant residence of 271 temporal and spiritual peers, and 800 members of the House of Commons. At present, about half-a-dozen peers, and 15 or 20 members of the House of Commons, have a settled dwelling within its precincts. Other persons of this exalted class of society, whom business or amusement may draw to the capital occasionally, take up their residence at the hotels, which are numerous in the city. The resident gentry of Dublin now amount to about 2000 families, including clergymen and physicians, besides nearly an equal number of lawyers and attorneys, who occasionally reside there. The families engaged in trade and commerce are calculated at about 5500, and the whole may yield a population of 60,000 or 70,000 in the higher and middle ranks of society. The change which has taken place, though injurious to commercial prosperity, has perhaps in an equal proportion proved beneficial to public morals; the general character of the inhabitants, which was once gay and dissipated, has now become more serious and religious, and those sums formerly lavished on expensive pleasures are now happily converted to purposes of a more exalted nature. Formerly there

were seven theatres well supported; at present the only one which remains is frequently thinly attended. Club-houses and gaming-tables are nearly deserted; and even among the lower classes vice of every kind has visibly diminished.' In 1831 the population of Dublin was 204,155; and in 1841, 252,726.

*Kilkenney*, the capital of the county of the same name, situated on the River Nore, was formerly a town of great consequence, as its ancient castle, the ruins of its embattled walls, and churches, testify. Till lately, it carried on a considerable trade in the manufacture of woollen cloths and blankets; but these branches have in a great degree fallen off, and the business is now confined to the retail of necessaries for its inhabitants, and the sale of the agricultural produce of the district. The city contains several good streets, which are respectably inhabited, both by private families and tradesmen; but the suburbs are miserable. The most conspicuous ornament of the city is the fine baronial castle of the Marquis of Ormond, full of historical associations, rising boldly over the Nore. The Cathedral of St Canice, built in 1202, is not excelled by any of the ancient ecclesiastical buildings in the kingdom, except St Patrick's and Christ-Church in Dublin. The town possesses a number of respectable schools, and various asylums and other beneficiary institutions. Near the town, as already noticed, there is a marble quarry of considerable local importance. Population in 1831, 23,741; in 1841, 23,625.

*Drogheda*, in the county of Louth, and situated on the Boyne, in the line of road from Dublin to Belfast, is a town of respectable appearance, and the seat of an industrious population. From the time the English settled in Ireland, this town was called *Tvedagh*, and considered of such importance, that parliaments were formerly held in it. In 1649 it was stormed by Cromwell, and the inhabitants put to the sword, except a few who were transported to America. Five steamers ply regularly between Drogheda and Liverpool or Glasgow, carrying out corn, cattle, sheep, pigs, and fowl, and bringing back cotton cloth, timber, leather, tobacco, salt, and iron. Drogheda contains three Episcopal churches—St Peter's, St Mary's, and St Mark's, which is a chapel of ease to St Peter's; four Roman Catholic chapels, two convents, and a friary. The chief civic buildings are a handsome tholsel, customhouse, mayoralty-house, jail, and linen-hall. The town does not bear a literary character: it has, however, four tolerably good booksellers' shops and a reading-room: there is also a mechanics' society in Drogheda. Its principal manufactures are a flax-mill, two foundries, salt-works, a distillery, and three breweries. There are, besides, several large flour-mills, and a soap and candle manufactory. There is a salmon-fishery on the Boyne, close to the town; and cod, haddock, plaice, soles, and gurnet, are abundantly caught along the coast. The linen trade is still carried on in Drogheda, though it is at present in a very depressed condition. The time of its greatest prosperity was from 1814 to 1820, during which period 4000 pieces of linen were averaged to be the weekly product. There was also a temporary revival of the cotton trade in this town; but in the commercial panic of 1825-6, many of the Drogheda weavers passed over to Manchester and Oldham, others went to France, and a large body emigrated to America, in consequence of which the cotton business ceased. The population in 1831 was 17,366; and in 1841, 19,260. In 1845 there belonged to the port 41 sailing vessels, with a tonnage of 3814; 5 steamers, with a tonnage of 2775; and the customs in the same year amounted to £9,372.

MUNSTER.

MUNSTER contains six counties, *Clare, Cork, Kerry, Limerick, Tipperary, and Waterford*, and may be considered as that part of Ireland in which the national character and the national habits of all kinds are maintained in their greatest purity. Some of the largest seats of population in the island, as the cities of Cork, Waterford, and Limerick, are situated in Munster. The

## IRELAND.

province contains many tracts of beautiful scenery, and one in particular, which is allowed to be unequalled in the kingdom—the celebrated lake district at Killarney.

The *lakes of Killarney* are situated in the bosom of the mountainous county of Kerry, and are annually visited by travellers from all parts of the island, as well as from neighbouring countries. They are three in number, of unequal size, and considerably varied with respect to surrounding scenery, though that may be described as generally of a mountainous character. Lough Lane, or the Lower Lake, by far the largest of the three, is skirted on one side by the level and well-cultivated country surrounding the pleasant village of Killarney; on the other side rise the Glens and Tomies Mountains. In this lake there are a number of wooded islands, one of which contains the ruins of an abbey, and another the remains of an ancient castle. On the shore, towards the east, is the beautiful ruin of Muckross Abbey. Divided from the Lower Lake by the fine wooded promontory of Muckross, but accessible by two channels of level water, is the Middle Lake, called also Turk Lake, from the name of the mountain at whose foot it reposes. Over and above the islands which stud the surface, the beauty of these two sheets of water may be said to consist in the irregular promontories and slopes, generally wooded, by which they are surrounded, and above which the mountains tower in sterile grandeur. In many nooks of the scenery, elegant mansions look out upon the lakes; in others the mountain streams are seen descending in glittering cascades. The Upper Lake, the third of the series, is 3 miles apart from the middle one, on a higher level, and totally embosomed amidst the hills. A stream descending from the one to the other can be passed in a boat; and at a particular place on the passage, it is common for tourists to have a bugle played, in order to enjoy the oft-repeating echoes which it awakes in the neighbouring hills. The Upper Lake, having the wooded heights of Dericunighy on one side, the round-headed Purple Mountains on the other, and at the head, the bare many-coloured ridge of Macgillicuddy Reeks, while the surface is broken by a variety of sylvan islets, presents a landscape of enchanting loveliness. In connection with the lakes, there is a narrow rugged vale named Dunloe, which is usually taken in by a tourist in a survey of this fine scenery.

Amongst other beautiful places in Munster, we can only particularise Glengarriff, a rugged and most picturesque vale near the head of Bantry Bay; the banks of the Blackwater, between Lismore and Youghal; the River Lee, below Cork, and the fine natural harbour (the *Cove of Cork*) in which it terminates; and the lofty iron-bound coasts of Clare, amidst which are some scenes of uncommon grandeur.

The soil in the southern parts of Limerick and Tipperary is perhaps not inferior in fertility to any portion of Europe. The Corkass lands of the former, and the Golden Vale of the latter, are celebrated for their extraordinary richness. These districts are chiefly appropriated to the feeding of black cattle. Wheat husbandry is cultivated throughout the limestone districts of Tipperary, Clare, and Limerick, while dairy-farming is followed in the mountain districts of Kerry and Waterford. The potato culture necessary to supply the wants of an over-dense population, is eagerly pursued throughout the whole province; and it is a deplorable fact, that a large portion of that population have no other food during the greater part of the year. The grass farms let in large divisions of from 150 to 400 acres, at from £2 to £3 per acre. In the dairies of the county of Cork, the great butter country of Munster, it is no uncommon thing to have from one to two hundred cows in profit; the advantage of which is, that a cask is filled at once by butter all of the same churning. The sweet thick cream only is churned, and that every morning. The pastures of these dairy-farms are highly manured, and are never broken up for tillage, experience having taught the dairy-farmers that the older the sward the richer is the milk.

Daily labourers are usually paid from 8d. to 10d. per

day; or if engaged by the year, from 6d. to 8d. In the latter case, it is supposed that the labourer has a house, and grass for a cow, at what is called a moderate rent, and which, in the estimation of the labourer, is equivalent to additional wages. The food of a great part of the Munster peasantry consists of potatoes; to this is usually added milk, and if they live near the sea, haak or herrings. In Cork, but few of the labouring poor have cows, because milk can be had in abundance at a moderate price at the dairies. It is, however, very customary to have ewes, which not only supply a tolerable quantity of milk, but furnish clothing. The women spin and dye the fleeces, and have them woven into thick frieze, and fulled at the village fulling-mill: from this practice, the southern Munster men are remarkably well clothed. The cottages, or rather cabins, are, generally speaking, wretched; but it may be stated that in the dwellings and furniture of the people there is a growing improvement. The character of the Munster peasantry may be considered as of mixed good and evil—the evil arising from a total want of restraint in early childhood, bad education, or, as frequently happens, none at all. Female education is peculiarly neglected; and it is deplorable to see marriages contracted when the wife has few or no capabilities for managing a family, and rendering her husband comfortable, or his house a happy home.

Generally speaking, the trade of Munster consists in the export of provisions and agricultural produce, as wheat, oats, and potatoes, to a large amount. There is on the Shannon an active fishery for trout, herrings, &c. and abundance of excellent fish are sent into Limerick, Ennis, Kilrush, and to the county of Kerry. Along the coast of Cork there is a fishery for pilchards, herrings, and other kinds of fish, which are caught in great quantities, so that frequently the farmers manure the fields with sprats.

### Chief Towns.

The leading towns of Munster are *Cork*, *Limerick*, and *Waterford*. The name *Cork* is derived from the Irish word *Corcah*, which signifies a marsh. This city, which ranks as the second in Ireland with respect to population and commercial importance, stands on the River Lee, which, through several channels, pours its waters into the harbour, from whence the tide flows to some distance above the town. The streets are built along the river channels, which, being all quayed, give the city somewhat of a Venetian character: of late years, however, the narrower have been arched over, and now only the main streams, in which the merchant vessels lie, are left open.

The Episcopal ecclesiastical buildings of Cork consist of seven parish churches, the Cathedral of St Fin Barry, St Luke's Chapel of Ease and Free Church, the Chapel of the Foundling Hospital, and the Church of St Michael's at Blackrock: two other churches are in progress. There are four Roman Catholic chapels, three new ones nearly completed, and four friaries. There are numerous dissenting chapels—two meeting-houses for Wesleyan Methodists, one for the Primitive Wesleyans, one for Anabaptists, two for Presbyterians, one for the Society of Friends, and two for two other small bodies of dissenters. A new Scotch church is in progress. The principal public buildings are—the Bishop's Palace, which stands on a height overlooking the town; a new jail, a little to the west of the city; the Customhouse, large and handsome barracks, the City Library, the Reading-Rooms, the infirmaries, the Chamber of Commerce, the Steam-Packet Office, and a well-built and spacious court-house, having in front a pediment supported on six Corinthian columns, and surmounted by an emblematic group of colossal figures. There is now in progress a new savings' bank, an extensive and ornamental building, but not more than half erected; also a new banking-house of cut stone for a branch Bank of Ireland; a new and showy corn-market house; and an extensive workhouse for the Poor-Law Union, about three-quarters of a mile from the city.

Cork boasts of many schools—the Blue-Coat Hospital, for twenty-two sons of reduced Protestants; the Green-Coat Hospital, for twenty children of each sex, to be brought up Protestants; the Cove Street Infant, Diocesan, Lancastrian, and Female Orphan Schools; the diocesan schools for the united diocese of Cork and Ross, a free school founded by Archdeacon Pomeroy, and one of the national colleges.

Among the charitable institutions in this city are—Bertridg's Charity, where are maintained seven old Protestant soldiers; Skiddy's Almshouse, where twelve aged women receive £29 yearly; Deane's Schools, where forty poor children are clothed and taught gratis. There is, besides, a masonic female orphan asylum, and several almshouses. Indeed, in proportion to its size, Cork bears a peculiarly high character for benevolence.

There are five societies here, whose objects are almost entirely scientific—the Royal Cork Institution, the Cuvierian, the Scientific and Literary Societies, the Mechanics' Institute, and the School and Library in Cook Street; one public subscription, and several circulating libraries; eighteen Protestant societies, devoted to religious purposes; four benevolent societies, for the relief of the distressed; five philanthropic societies, two lunatic asylums, and a school for instructing the deaf and dumb poor in George's Street.

The chief exports of Cork are grain, butter, cattle, and provisions; its chief imports, wine, tea, sugar, and coals. Steam-vessels communicate between Cork and Dublin, Bristol and Liverpool; and steamboats also ply daily between Cork and Cove. The population of Cork, according to the census of 1831, was 107,016; in 1841, 106,055. In 1845 there were 384 vessels belonging to the port, with an aggregate tonnage of 40,000; 14 steamers, with a tonnage of 2900; and the customs' duties exceeded £302,000.

*Limerick*, the chief city of the west of Ireland, is situated on the Shannon, near the place where that noble river expands into an estuary. It consists of the Old and New Town, respectively situated on the north and south sides of the river, and connected by an elegant modern bridge. The new city contains many good streets, filled with handsome shops; but the Old Town is confined, dirty, decayed, and inhabited by a very miserable population. Limerick contains a handsome cathedral of some antiquity, situated in the old part of the city, six Episcopal churches and a chapel of ease, meeting-houses belonging to the Presbyterians, Independents, and the Society of Friends, with five Roman Catholic chapels, three friaries, and one nunnery. The principal public buildings are the Exchange, the City Courthouse, the City and County Jail, the Police Barrack, the Customhouse, the Commercial Buildings, the Linen-Hall, the Market, and two banks. Though Limerick is not a particularly literary city, it has an excellent library and some very good booksellers' shops. The principal school at Limerick is the Diocesan, but there are many private day and boarding schools. There are many charitable institutions—as the County Hospital; the House of Industry for the aged and infirm, widows, orphans, young females, and deserted children; the Corporation Almshouse; Dr Hall's and Mrs Villiers's Almshouses.

With regard to the trade of Limerick, it has been observed, that though it has increased with the extension of the city, it has done so by no means in an adequate proportion when its peculiar advantages are considered; the Shannon, which connects it with Clare, Kerry, Waterford, and Tipperary, affording it innumerable commercial facilities. The quays of Limerick are nevertheless a scene of considerable bustle, though chiefly frequented by vessels for the export of the native produce. Provisions to the amount of 75,000 tons are here shipped annually. In 1845 the port had 114 vessels, with a burthen of 15,000 tons; and the gross receipt of the customs amounted to £177,000. The population of Limerick in 1831 was estimated to be 66,555, and in 1841, 65,296.

*Waterford*, the chief town of the county bearing its

name, and a large seaport, is situated on the Suir, a few miles from its junction with the sea. Native produce, to the value of £2,000,000, is annually exported from this city; but the imports are comparatively unimportant. There is here a fine cathedral, founded by the Ostmen, and endowed with lands by King John, and several churches, meeting-houses for the Presbyterians and the Society of Friends, a French church for the Huguenots, and several abbeys and friaries. The principal buildings are the Bishop's Palace, the Exchange, and the City Jail. Amongst its schools are the Latin Free School, and the Blue-Boys' Free School, in which seventy-five are instructed and partly clothed gratis, and the boys apprenticed to different trades. The population in 1831 was 28,820; in 1841, 29,288. In 1845 there belonged to the port 186 sailing vessels, whose tonnage amounted to 23,000; 4 steamers, with a burthen of 1000 tons. The gross receipt of customs' duties exceeded £173,000.

#### ULSTER.

The most northerly of the provinces is **ULSTER**, containing the counties of *Antrim, Armagh, Cavan, Donegal, Down, Fermanagh, Derry, Monaghan, and Tyrone*. The province of Ulster is hilly. The scenery is in general picturesque, especially in the vicinity of its chief towns, Derry, Belfast, and Armagh. In the county of Antrim, the country from Glenarm to Bengore Head presents a succession of striking and romantic views. The most remarkable feature of this scenery is the peculiar conformation of the basaltic columns with which it abounds, and of which the arrangement is strikingly displayed in Fairhead and the *Giants' Causeway*. Bengore, one of the promontories of the Causeway, lies about 7 miles west of the little town of Ballycastle: though generally described as a single headland, it is composed of many small capes and bays, each bearing its own proper name, and of these capes the most perfect is *Pleaskin*. The summit of Pleaskin is covered with a thin grassy sod, which lies upon the rock, the surface of which is cracked and shivered. About 10 or 12 feet from the top, the rock begins to assume a columnar character, and standing perpendicularly to the horizon, presents the appearance of a magnificent colonnade, supported on a foundation of rock nearly 60 feet in height. About 8 miles from Pleaskin is *Fairhead*, the easternmost head of the Causeway, which presents a huge mass of columnar stones, of coarse texture, but many of them more than 200 feet in height. Some of these gigantic stones seem to have fallen from the top, and now present to the eye of the spectator the appearance of groups of artificial ruins. The part which may more properly be called the *Giants' Causeway* is a kind of quay, projecting from the base of a steep promontory some hundred feet into the sea: it is composed of the heads of pillars of basalt, which are placed in close contact with each other, forming a sort of polygonal pavement, somewhat like the appearance of a solid honeycomb. The pillars are jointed, and their articulation curiously exact, the convex termination of one joint always fitting with precision into a concave socket in the next. Within about 2 miles of the *Giants' Causeway* stands Dunluce Castle, situated on the summit of a rock whose base is washed by the ocean, by the ravages of which great part of the building was suddenly swept from its foundation. The mansion and offices stand upon the mainland, divided from the fortress by a deep cut which separates the rock on which the castle is placed. Over this chasm lies the only approach to the building, along what was one of the walls of the drawbridge: should the passenger miss his footing on this narrow path, there is not the slightest protection on either side to save him from the abyss beneath.

The soil of Ulster varies much. In the counties of Armagh, Down, Antrim, Derry, and Monaghan, it passes from a deep rich fertile clay to a dry sandy or gravelly loam; while in Donegal, Tyrone, Fermanagh, and Cavan, a great proportion of it is cold, wet, and

## IRELAND.

spongy. Tillage is, in general, in an improved state throughout this province; and though the old Irish plough and the slide car are still occasionally used in the remoter parts, many of the modern implements of husbandry have been introduced, especially in Down and Londonderry. The English spade has nearly displaced the long or one-sided spade; the angular harrow and the thrashing-machine are much in use; and the Scotch plough has almost superseded the heavy Irish one. The corn crops most general are oats, bere, barley, and a small proportion of wheat. Barley is in Derry said to pay the summer's rent, and flax the winter's. Potatoes are largely planted by rich and poor, and gentlemen-farmers cultivate turnips and mangel-wurzel. Lime and peat are the most usual ingredients of the manure employed in the inland districts; while in the maritime counties, sea-sand, seaweed of different sorts, and various kinds of shells pulverised, are used in addition. From the wetness of the soil, in some of the northern parts of Monaghan, the manure is usually carried to the fields in baskets, called *bar docks*, which are slung over asses' backs or the shoulders of the poor women. A small but hardy race of horses is reared in the island of Rathlin, or Raghery; and the old Irish sheep still prevails in and near Carey, in the county of Antrim. Pigs, goats, and donkeys, are numerous, the latter being much used in the counties of Cavan and Monaghan. A good deal of butter is sent to the markets of Belfast, Antrim, and Derry, from the various dairies scattered through Ulster.

Whatever were the manufactures of Ireland before the time of James I., they were swept away in the long series of wars between government and the local chieftains in the days of the Tudors; and the Scottish settlers in the north of Ireland, and those English whom Boyle, Earl of Cork, brought into Munster, may be considered the introducers of nearly all the manufactures that now exist in Ireland. During the reigns of Charles I. and II. much attention was paid to them; and the exertions of Lord Strafford, Sir William Temple, and the Duke of Ormond, caused the establishment of the linen trade to be attributed successively to each. The Duke of Ormond not only procured several acts for its encouragement, but sent Irishmen to Flanders to be instructed in the details of the flax manufacture; and also established a linen factory both at Chapelizod, near Dublin, and at Carrick-on-Suir. In the reign of William III., the linen business rose to still greater importance, from the compact between the English and Irish merchants to discourage the woollen and promote the linen trade; for which purpose they procured a statute to be passed, levying additional duty on Irish woollen goods, from a jealous fear that the prosperity of the Irish woollen trade was inconsistent with the welfare of that of England. Another impetus was given to the linen trade by the emigration of the French manufacturers, after the Edict of Nantes, of whom a large number took refuge in Ireland; and Mr Louis Cromelin, a leading manufacturer, obtained a patent for improving and carrying it on, and his efforts were crowned with considerable success. In the 9th year of Queen Anne, a board of linen and hempen manufactures was established, and linen allowed to be exported, duty free. In the 8th of George I., a grant was given to build a linen-hall, and another to encourage the growth of flax and hemp. Previous to 1778, bleached linen was sold in the fairs, the manufacturer being the bleacher; but when the manufacture extended, bleaching became a separate business. Considerable sums had been from time to time voted by parliament for its support; and during the eighteenth century the trade continued to advance, until the check it received during the American war. On the re-establishment of peace it revived, and was at its greatest height from 1792 to 1796. Since this period it has considerably increased, and though deprived of all artificial props, in the form of bounties, is now a flourishing department of industry. Belfast is the great centre to which the linens, not only of Ulster, but also of the weaving districts in the west

of Ireland, are sent for sale; and from hence large quantities are exported to foreign countries. The linen trade prospers at Castlewellan, Rathfriland, and Banbridge, in the county of Down, and also at Lurgan in the county of Armagh, where the weavers are at once weavers and manufacturers. At Dungannon, in the neighbouring county of Tyrone, it has greatly declined, and is in Donegal chiefly confined to those who work for farmers or market sale.

The province of Ulster was also the seat of the first cotton manufactory introduced into Ireland. In 1777 the manufactures were in the lowest state of depression. To give them some stimulus, Mr Joy conceived the plan of introducing cotton machinery from Scotland; and a firm for this charitable purpose was formed, of Joy, M'Cabe, and M'Craken; and a mill for spinning twist by water was erected by them at Belfast in 1784, at which time the manufactory may be said to have been established; and so rapidly did it spread, that in 1800, in a circuit of ten miles, comprehending Belfast and Lisburn, it gave employment to 27,000 individuals. But from want of assistance at home to protect it, and the embargo laid on American goods, which inundated Ireland with English manufactures, the trade has declined, and the cotton manufactory is now almost altogether confined to the county of Antrim. Through the early part of the present century, it was carried on to a considerable extent in Drogheda, Collon, Strafford, Mountmellick, Limerick, and Bandon. Belfast was, however, the place where most skill and capital were expended; as the trade increased there, it declined in other parts of the kingdom; and though large manufactories have formerly been established at Clonmel, Portland, and Limerick, it may for all practical purposes be considered as extinct in the other parts of Ireland.

Wherever the linen trade is in operation, the people have constant employment, in consequence of being able to fall back upon their looms when agricultural work is not in demand. They may be said, in common years, to enjoy a competency—that is, a sufficiency of food, raiment, and fuel. But in the western parts of Ulster—as, for example, the mountainous districts of Tyrone, Donegal, and Derry, where the linen manufactory does not exist to any extent—the labouring-classes are not much better off than in the three other provinces. However, speaking of Ulster generally, it may be said the lower classes have more self-respect, more industry, more desire for advancement in life, than in other parts of Ireland. In fact, they are a better educated, and therefore a more improving people. As may be expected, their taste for comfort operates in the economy of their houses and farms; and except in the mountainous districts above alluded to, where old habits still maintain their ground, the Ulster peasantry may be considered as a respectable class in society. The average rent of arable land is from £2 to £3 per acre, usually rising in the immediate neighbourhood of towns to £5 or £6. The wages in Ulster vary from 6d. to 9d. a day in winter, and in summer from 10d. to 1s. a day, without diet. The food of the peasantry is chiefly potatoes, oatmeal porridge, oaten bread, milk, and fish, which those who live near the sea vary with that species of sea-weed called the edible *alga*.

The salt-water fisheries of Ireland cannot be said to have ever thriven. Under the former system of the Irish Parliament, of giving bounties, large sums were at different times voted for their encouragement; but by this there was no real strength given, and on the withdrawal of these bounties, things fell below their natural level, and the sea-fisheries became altogether inefficient for any purpose but that of supplying the localities surrounding the fisherman's dwelling. The fishery laws are now enforced with regard to both the sea and river-fishing, and therefore there is reason to believe that this branch of industry is on the increase, and, if properly managed, will become one of the chief means of benefiting the island. The river-fisheries, though less productive than under better management they might have been, yet form in several parts of

Ulster a lucrative source of property. The lakes and rivers abound with trout, pike, perch, eels, and char; and on the Bann, the Foyle, and the Ballyshannon in Donegal, are established very successful salmon-fisheries. Formerly, whales were not unfrequently, and still are, though but seldom, taken at the coast-fisheries in this province. The salmon-fisheries of the Foyle and the Bann were early celebrated. In Phillips's manuscript they are stated to have been let from 1609 to 1612 at £666, 13s. 4d. a year; for three years at £860; for eleven years at £1060; and for twelve years, ending at Easter 1639, at £800. The right of fishing the river Foyle, so far as Lifford, is vested in the Irish Society by the charter of Londonderry, granted by James I. in 1613. The increase of the quantity of fish taken since the introduction of stake-nets is very considerable. The salmon for exportation to London and to Liverpool are packed with ice in boxes, fifteen salmon, weighing together about 90 lbs., being put into each case. In a report made to Sir William Petty about 1682, it is stated that the fishing for salmon in the Bann River, and so in all the salmon-fisheries, begins with the 1st of May, and ends on the last of July. But by the present law, the season now begins on the 1st of February, and ends on the 1st of September, seven months being open and five close. The Bann fishery has of late years been much neglected; but under the spirited and judicious management of Charles Atkinson, Esq., it has been much improved during the last year.

Chief Towns.

The chief towns in Ulster are *Belfast* and *Antrim*, in the county of Antrim; *Londonderry* or *Derry*, and *Coleraine*, in the county of Londonderry; *Donegal*, in the county of the same name; *Strabane*, in Tyrone; *Armagh*, in Armagh; and *Newry*, *Lisburn*, and *Downpatrick*, in the counties of Antrim or Down. Without reference to counties, Belfast, Lisburn, Newry, Armagh, and some places of smaller note, may be said to form a cluster of towns chiefly devoted to the linen manufacture, and all occupied by a population who, for generations, have been noted for their industry and peaceful habits.

*Belfast* is esteemed the principal town and seaport in this province of Ireland. It is advantageously situated on the west side of the Lagan, where that river swells into an estuary called the Bay of Belfast: distance from Dublin 85 miles. The ground on which the town stands is flat, while the beautiful and fertile environs on the western side of the vale are bounded by a picturesque range of mountains. Within the town, the opposite shores of the Lagan is reached by a long stone bridge, which also forms the egress from Belfast towards Donaghadee. Although this portion of Ireland is inhabited chiefly by Scotch, or their descendants, Belfast, like Dublin, is essentially an English town in external aspect, being built of brick, and having throughout a neat and regular appearance, with many handsome shops. The prosperity of Belfast is dated from the revolution of 1688, when religious and political tranquillity settled upon that part of Ireland. Belfast is in Ireland what Glasgow is to Scotland, and Liverpool to England. In manufactures, it is now the great depôt of the linen business, and the seat of the cotton trade, having within itself all the various branches necessary for producing and finishing these fabrics, from the finest cambric to the coarsest canvas. There are in Belfast and its suburbs fifteen steam-power mills, for the spinning of linen yarns. Among these, the factory of Mulholland and Company, employing 800 persons, spins 720 tons of flax annually, the yarn of which is worth £80,000. The hand-spun yarn sold on commission in the Linen-Hall (a cluster of buildings devoted to the use of linen factors), produces about £100,000 a year. The cotton trade is declining, several of the mills being employed in spinning flax; and there are now only six cotton-mills in the town. There are also extensive corn-mills, breweries, distilleries, and tan-yards, with manufactories of machinery, cordage, glass, iron, soap, candles, tobacco, &c. for home

use and exportation. In commerce, its exports and imports are extensive; the amount of duties paid at the customhouse of late years averaging nearly £370,000. The number of vessels lately belonging to the port was 386, the aggregate burthen of which was 58,500 tons. Latterly, great improvements have been effected for the accommodation of the shipping, by deepening and contracting the harbour, and furnishing handsome and substantial quays, wharfs, and docks. The port usually exhibits a busy scene of industry, by the daily sailing and arrival of ships and steam-vessels. Ten steamers sail regularly—four to Glasgow, three to Liverpool, two to London, and one to Dublin. In the retail trade, the numerous branches are carried on in a spirited and tradesmen-like manner; and the various markets for the sale of the rural produce, which is brought in large quantities to town, are well conducted; in a word, the whole system of trade and industry is on an efficient scale, and equals that of any town of similar size in England or Scotland. The prosperity of the town is likely to be augmented by a railway lately opened, which is designed to proceed to Armagh.\*

Belfast abounds in Presbyterian and other Dissenters. The Episcopal places of worship are only two (some authorities say three) in number; but there are ten Presbyterian meeting-houses; there are also two meeting-houses of Independents; the Methodists, four; the Society of Friends, one; and the Roman Catholics, two. The town possesses some excellent charitable and humane institutions: the principal are—a poor-house for the aged and infirm, a house of industry, a lunatic asylum, an institution for the blind and for deaf mutes. This institution is on the same plan as that of Liverpool. The blind are employed in weaving and basket-making, and lately, by the introduction of raised letters, they have been instructed in reading. In 1824, there were in the town and parish sixty-three schools of all kinds, at which 2152 males and 1666 females were educated, exclusive of the Royal Academical Institution, which in 1825 contained 462 boys in its various classes. This institution originated in 1807, in a voluntary subscription of the inhabitants, by whom a fund was raised of above £25,000, to which the late Marquis of Hastings added £5000 for its erection and the endowment of its teachers and professors. It consists of two departments—one elementary, the other for the higher branches of science and literature. This establishment is directed by a president, four vice-presidents, twenty managers, and eight visitors, chosen by the proprietary. The chairs in the collegiate department are eight, embracing Divinity, Moral and Natural Philosophy, Logic, Mathematics, Greek, Latin, Hebrew, and a lectureship on Irish. The object of this academy was to give cheap home education to those who had heretofore frequented the Scottish colleges. The Synod of Ulster receives the general certificate of this institution as a qualification for ordination, and it may therefore be now considered the great seminary for the Presbyterian Church in Ireland. The Belfast Academy had been founded some time previously by private subscription.

Of literary societies, Belfast possesses the Society for Promoting Knowledge, founded 1788; the Literary Society for Improvement in Literature, Science, and Antiquities, founded 1801; and the Natural History Society, founded 1821. The town has lately received the valuable addition of a botanic garden, on a large scale, and laid out in an exceedingly tasteful manner. It was established and is wholly supported by the inhabitants of Belfast, and affords a pleasing proof of their spirit and liberality. The population in 1821 was 37,277; in 1831, 53,287; and in 1841, 75,308.

*Londonderry* ranks next to Belfast. Besides being a seaport of considerable importance, it is the seat of a bishop's see. It is situated on the west bank of the

\* We have been indebted for a number of these particulars to 'The Tourist's Guide to Ireland,' a highly creditable work, published by Messrs W. Curry, Jun. and Co., Dublin.

Foyle, a few miles above the point where that river spreads into the harbour of Loch Foyle, and is distant 146 miles from Dublin. The original town, built by Sir Henry Dowers about 1603-4, was burned by Sir Cahir O'Dogherty in 1608; and the present city may be considered as deriving its origin from the London plantation, which was the immediate result of that catastrophe. The walls of Derry are described by Pynnar as 'excellently made, and neatly wrought; the circuit thereof about 284 perches, and in every place the wall being 24 feet high and 6 in thickness;' and after a lapse of more than two centuries, these fortifications retain their original form and character. The north-west bastion was demolished in 1824, to make room for a market; and in 1826 the central western bastion was modified for the reception of Walker's Testimonial; but the guns used during the celebrated siege are still preserved in their original places. The total number of cannon remaining in the city and suburbs is about fifty; and in the court-house yard stands *Roaring Meg*, so called from the loudness of her report during the siege. This cannon is 4 feet 6 inches round at the thickest part, and 11 feet long, and is thus inscribed—'FISHMONGERS, LONDON, 1642.'

The chief of the ecclesiastical buildings is the Cathedral. For nearly twenty years after its plantation, Derry was without a proper place of worship, part of the ruined church of St Augustine being employed for that purpose. At length a royal commission of inquiry was appointed, which, in 1628, reported that the corporation of London had begun to build a fair church in Derry, and in 1633 its erection was completed. This event is recorded in a tablet, which was originally placed over the door of the porch of the old cathedral, but is now over that of the belfry, bearing the following couplet:—

'If stones could speak, then London's praise should sound,  
Who built this church and city from the ground.—A. D. 1633.'

The other principal places of worship are—a chapel of ease, a free church, several Presbyterian meeting-houses, a Wesleyan chapel, a Primitive Wesleyan Methodist chapel, also Reformed Presbyterian, Seceding, and Independent chapels, and a Roman Catholic chapel, which can accommodate 2000 persons. The principal buildings in the city are the Bishop's Palace, the Public Library and News-room, the Lunatic Asylum, the Jail, and the Corporation Hall. Of its various manufactories, the chief are two great distilleries, and two corn-mills, one worked by a steam-engine of eighteen, the other by one of twenty horse-power. The public schools in Derry are—the Diocesan, the Parochial, the Presbyterian, the Meeting-house, St Columb's, the Barracks, the Infant School; and besides these are many others, public and private. There is here a branch of the London Bible Society, the Londonderry Literary Society, and one for promoting religious, moral, and historical knowledge. There are also the Londonderry Farmers' Society, and the Mechanics' Institution. The port carries on a considerable traffic, both with respect to imports of foreign and British produce, and exports. The estimated value of the exports of Irish produce is above £1,000,000 sterling per annum. The population of Londonderry in 1831 was 10,130; and in 1841, 15,196. In 1845 the shipping belonging to the port exceeded 6200 tons; and the gross customs' duties £105,800.

The city of *Armagh*, situated in an inland part of the country, is of considerable local importance. It is placed in the midst of a rich and beautiful district, the face of which is singularly varied by detached hills, some of which are more than 1000 feet in height. This character of country stretches from Lough Neagh in the north to the north-western part of the county of Meath in the south, and is well watered by lakes and streams, and, generally speaking, richly furnished with wood. The city stands on a hill, which is crowned by the old cathedral, around which the town has gradually arisen. Within these few years, several

handsome buildings have been erected, with cut stone fronts—the Court-house, the Jail, the Presbyterian Church, Primate Stewart's Free School, founded and liberally endowed by him, and well carried on; the National School, and the Savings' Bank. The cathedral has been re-edified within these five years, at an expense exceeding £30,000, in the pointed Gothic style, for the most part in very good taste; the organ is a remarkably fine one, and the choir excellent. The roads, in all directions, are admirable; and in the laying-out of the new ones, they are carried round instead of over the hills. There is water-carriage from both Belfast and Newry by lake and canal, to within four miles of the city; the streets have flagged footways, and are well lighted with gas. About forty years since, the population was only 1000; in 1841 it was 10,245. The archbishop of Armagh, primate of all Ireland, resides close to the town, as do also a large number of clergymen attached to the cathedral, as well as many respectable gentry. Near Armagh stands the Observatory, built and endowed by Primate Robinson, whose munificence greatly contributed to the advance of science and improvement of the whole diocese.

## CONNAUGHT.

CONNAUGHT, the smallest of the four provinces, contains but five counties, those of *Lairim*, *Roscommon*, *Mayo*, *Sligo*, and *Galway*. There are in this province large tracts of mountainous and sterile land, especially in the western parts of the counties of Galway and Mayo. The peninsula formed by the western part of the first of these counties is named *Connemara*, and is famed for its scenery, which somewhat resembles that of Argyleshire. It may be described as a vast tract of mingled bog, lake, rocky moorland, and mountain, bounded and partially penetrated by deep inlets of the sea, resembling the fiords of Norway. The principal lake is Lough Corrib, which is 20 miles long, full of islands, and surrounded by an extensive rocky desert, bearing no small resemblance to those of Arabia. Between this lake and the western extremity of Connemara, there is a range of tall swelling green hills, called the Twelve Pins of Bunabola; and to the north of these is an estuary famed for its wild scenery, named the Killery, many miles in length, and connected with the Atlantic by a passage only 30 feet wide. Connemara contains a small, scattered, and primitive population, unusually full of superstitious and old feudal feelings. Besides Clifden, a modern fishing-village on the west coast, there is scarcely any such seat of population in the district. There are, however, a few homely inns for the accommodation of the numerous tourists who flock thither during summer.

From the high grounds near Westport is obtained a view of Clew Bay, a magnificent sheet of almost enclosed water, full of islands, and bounded by lofty mountains, amongst which the most conspicuous are Croagh Patrick and Nephin. The islands of Clare and Achill bound the scene towards the west. In some states of the weather, and particularly when a summer sun is calmly descending on Clare, the view of Clew Bay is one of extraordinary beauty. The islands are said by the common people to be as numerous as the days in a year, but in reality are only about a hundred. Croagh Patrick is regarded with superstitious feelings by the peasantry, as the spot where their tutelary saint was accustomed to preach.

Amidst the great tracts of wild ground in Connaught, there are a few other spots of an unusually attractive character. The scenery round Lough Allen, out of which the Shannon flows, is extremely pretty, as is also that near Boyle, at the foot of the Curlew Mountains. At Lough Gill, near Sligo, a lake bearing a strong resemblance to the upper lake of Killarney, and the little Bay of Ardnaglass, into which falls the cataract of Ballysedare, are scenes of peculiar beauty. Much of the surface of Galway is flat, showing, for twenty miles together, a succession of narrow limestone rocks, like parapet walls of three feet high, placed in

parallel lines to each other, at distances of from three to ten feet: the intermediate spaces, though apparently but a waste of rock and stone, supply the finest sheep pasture in the kingdom.

The great central limestone district of Ireland occupies the southern portion of this province, which to the eye forms an exception to the general character of limestone countries, appearing so exceedingly barren, that in passing over tracts of Galway and Mayo, the traveller almost doubts whether he is not journeying over a great cemetery covered with tombstones, rather than over places where the sheep could find pasture or the peasant plant potatoes. There are, however, some exceptions to this prevailing sterility, for nowhere are finer sheep-walks found than in some parts even of the southern counties of Connaught. The tillage of this province is principally confined to oats and potatoes, as best suited to the shallow mountain bog-soil, which so largely prevails in the western baronies. The extreme moisture of the climate is so inimical to the growth of wheat, that except in a few parts of Galway, Connaught cannot be said to grow its own bread-corn. There is a great export of oats and potatoes from the ports of Galway, Westport, and Sligo. With regard to husbandry, though it certainly is improving, it is yet much inferior to that of the other provinces. The landholders pride themselves on the breed of long-wooled sheep, their great source of wealth; and the celebrated Fair of Ballinaloe, where from 80,000 to 100,000 are usually sold, year after year exhibits an improvement in this branch of rural economy. Horned-cattle, and horses, especially hunters, are also bred extensively in Galway. What has been said of Munster applies in a still more aggravated degree to Connaught. The property of an absentee landlord is usually divided into portions ruinously small; and if the proprietors do not quickly interfere, deplorable consequences must result from the subdivision system. The grazing farms are let in large portions, which it is the policy of the farmer not to diminish. Rents vary from £1 to £1, 10s. an acre, except in the vicinity of the towns, where they usually rise to £2 and £3; and wages are from 10d. to 1s. a day in summer, and from 8d. to 10d. in winter.

There have been many attempts to introduce the linen manufacture into Connaught, and markets for its sale were established in Sligo, Castlebar, Westport, and Galway; but though it thrives to an extent sufficient to supply the rural population, there is reason to believe that little if any linen is exported from the province. There is, from the ports above-mentioned, a pretty large export of oats, whisky, and potatoes.

The peasantry in Connaught are as poor as poverty can be without amounting to destitution; and except in the mountain districts, their situation is daily becoming worse—so much so, that poverty, in times of scarcity, which, on an average, occur about once in seven years, increases to destitution, and appeals to the richer members of the empire to save the labouring classes from actual starvation become unavoidable. The food of those who are the best off is generally dry potatoes, with occasionally a herring or an egg. In Connaught, the indigent peasant is reduced to a state of greater poverty, by grasping at the temporary relief afforded by the system called by the Irish name of *gambeen* (exchange), of which the principle is to furnish provisions to the poor, allowing time for payment, but generally charging an exorbitant interest. This system has led to the most deplorable results.

There is a good salmon-fishery near the town of Galway, and one for cod, hask, and haddock, which, from the poverty of those engaged in it, prevents them from providing sufficient tackling for their boats, and is thus less productive than it might be. In some years the sun-fish, or basking-shark, are abundant off the shores of Galway, and much excellent oil is produced; but this fish is so capricious, that the fishery cannot be looked to with any certainty. The salmon of Ballinahinch are regularly sealed up in tin cases by the gen-

tleman who farms this fishery from Mr Martin, the principal proprietor of the country. There is a very productive salmon-fishery below the thriving town of Ballina, on the river Moy, from which large quantities of salmon are sent to the London market.

#### Chief Towns.

*Galway*, reckoned the capital of the west, and, in point of population, the fifth town in the kingdom, is situated in a valley lying between the bay which bears its name and Lough Corrib. The town is of considerable antiquity, and consists of streets and lanes huddled together without any regard to comfort or convenience. The whole partakes of the appearance of a Spanish town, the result probably of its early intercourse with Spain; and a small open space near the quay retains the name of *Spanish Parade*. The principal ecclesiastical buildings are the parish church of St Nicholas, founded in 1320, a Presbyterian meeting-house, and the Roman Catholic chapel. The Franciscans, Augustines, and Dominicans have monasteries here. The chief public buildings are—the County Court-House, a handsome cut-stone edifice, erected in 1815, with a portico of four Doric columns; and the Tholsel, built during the civil wars of 1641. The schools in Galway are mostly under the superintendence of the Roman Catholic religious orders. There is also one on the foundation of Erasmus Smith, one belonging to the National Board, and about sixteen parish schools. Galway possesses a house of industry, an asylum for widows and orphans, a Protestant poorhouse, and a Magdalen asylum, which is supported by two benevolent Roman Catholic ladies.

The chief manufacture of Galway is flour. There are a bleach-mill and green on one of the islands, an extensive paper-mill, and several breweries and distilleries, in the town. The exports consist principally of grain, kelp, marble, wool, and provisions; the imports of timber, wine, coal, salt, hemp, tallow, and iron. In 1845, the vessels entered inwards numbered 141, of an aggregate burthen of 13,000 tons; while the vessels cleared outwards amounted to 145, with a tonnage of 15,531. In 1840 a splendid dock was opened, from which great expectations are formed of the increase of trade. A steamer in this bay is highly necessary for towing out vessels in adverse winds. In 1845 there were 18 vessels belonging to the port, with a tonnage of 2700; and the gross customs' duties amounted to £28,000. In 1831, the population of the town was 27,775; and in 1841, 32,511.

Across the country in a northern direction, and also situated at the head of a bay bearing its name, stands *Sligo*, a town of a much smaller population than Galway, but more important as respects its commerce. It has carried on for several years a considerable trade, both export and import, and is still increasing, notwithstanding the bad state of its harbour. The exports are wholly limited to agricultural produce, and of late years have amounted to about 60,000 pigs, worth £200,000; 6000 black cattle, worth £60,000; 50,000 firkins butter, worth £125,000; 22,600 tons of oats, worth £132,000; and 12,000 tons of oatmeal, worth £132,000. In 1845, Sligo had about 26 vessels, with a tonnage of 3000; and the gross receipts of customs' duties was £31,000. The retail trade is extensive, articles of every description in demand being supplied to a large and populous district. The streets in the older part of the town are narrow, dirty, and ill-paved, and badly suited to the bustle of an export trade. But convenient markets have been erected, and the extension of the town, by regularly-built wide streets, is expected to remedy the inconvenience and irregularity of the older parts. Some good public buildings embellish the prominent points in and about the town, and the river Garwogue, which bears the surplus waters of Lough Gill to the bay, and turns several large flour-mills in its course, is a fine feature in the scene. The suburbs are beautiful and picturesque. In 1831 the population was 15,152; but in 1841 it was only 14,318.

## ASIA—EAST INDIES.

ASIA—the most extensive, the most diversified, and, so far as the early history of mankind is concerned, the most interesting of the great divisions of the globe—is situated between lat. 1° 28' and 78° north, and long. 26° and 190° east. It thus occupies the greater portion of the Eastern Hemisphere, and is bounded on the north by the Arctic Ocean; east by the Pacific; south

by the Indian Ocean; and west by Africa and Europe—being separated from the former by the Red Sea and the Isthmus of Suez, and from the latter by the Mediterranean, Black Sea, Caucasus chain, Caspian Sea, and the Oural Mountains. The region thus enclosed lies compactly together, the only irregularities in its bounding outline being that succession of peninsular pro-

jections and intervening gulfs which give character to its eastern and southern seaboard. Its greatest length, along the 40th parallel, is 5500 miles; the greatest breadth, from Cape Romanis in the Malayan Peninsula to North-East Cape, along the 104th meridian, 5300 miles; and area, at the lowest estimate, 16,152,000 square miles, or nearly four times that of Europe.

### SUPERFICIAL FEATURES.

The physical aspect and construction of the continent exhibits every species of diversity—vast mountain-chains and elevated table-lands, broad level steppes and sandy deserts, luxuriant plains watered by the largest rivers, tracts doomed to everlasting snow, or to scorching sterility, salubrious valleys of incessant verdure, and noisome jungles of the grossest growth. With such a variety of character, it is impossible to speak of it as a whole, and consequently geographers distinguish the following well-defined zones:—

1. *Northern or Russian Asia*, including the whole of the continent north of the Altai and Iablonnoi Mountains—a region traversed by large rivers, bleak and barren, suffering under an intense cold, thinly peopled, and almost physically incapable of improvement. West of the river Yenesei this tract presents a succession of

*steppes*; that is, level countries with a sandy, gravelly, or clayey bottom, destitute of trees, unless along some of the river banks, and covered partly with low shrubs, and partly with coarse grass, which affords in summer a scanty pasture. Here also there are numerous swamps and salt-marshes, and only the first stage of the ascent towards the Altai is capable of a rude cultivation. Between the Yenesei and Lena the country has more of an undulating character, is covered with forests of pine and birch, has finer pastures, but, in consequence of the cold, offers no facilities for agriculture. Eastward of this the surface becomes high, bleak, and only in sheltered situations affords a stunted growth of birch, willow, and pine; while all north of the Arctic Circle the country is one flat bog-moss or *tundra*, interspersed by lakes, frozen for ten months of the year, and even during summer the thaw does not penetrate beyond eight or ten inches.

2. *Central Asia*, lying principally between the 30th and 50th parallels—having the Altai and Iablonnoi Mountains on the north, the Himalaya and Hindoo Koosh on the south, the Khing-Khan and Yun-Ling ranges on the east, and the Highlands of Tartary on the west. This region comprises Mongolia, the Desert of Kobi, Thibet, and part of Tartary, and consists of a series of

ascending plateaux, diversified by mountain ridges, and intersected by valleys. That of Mongolia and Kobi, for example, is supposed to have an absolute elevation of not less than 3000 feet, with its ridges rising to 10,000 feet or upwards; that between the confines of China and Thibet is still more elevated, and more diversified by ridges; while that of Thibet consists of several steps, the lowest of which is said to have an absolute elevation of not less than 10,000 feet, and the highest from 12,000 to 14,000 feet. On the Tartary side the country again begins to fall, and is more diversified by sandy steppes, lakes, hill-ridges, and fine fertile valleys. The whole of the central table-land, however, must not be considered as bleak and monotonous desert; for although the higher ridges are covered with perpetual snow, and much of it is rugged and sterile, yet there are many plains affording good pasture, and sheltered valleys which produce grain, cotton, wine, and various fruits.

3. *Eastern Asia*, consisting of Mandahuria, China Proper, and the adjacent island of Japan; upon the whole, a low-lying and somewhat arid region, though traversed by several of the largest rivers in the world. Mandahuria is rather hilly and desert, particularly the parts towards the west and north; and the eastern coast is fenced by a rugged ridge which descends abruptly to the sea; but the interior is well-wooded, and though enduring a severe winter of four months, is capable of producing rice, cotton, and silk. China, on the other hand, is more uniform in surface, if we except the western provinces, which are intersected by numerous ramifications from the Yun-ling, Pe-ling, and other mountain-ranges. Eastward, towards the embouchures of the Hoang-Ho and Yang-tse-Kiang, the country assumes the character of an alluvial plain, extending from the 30th parallel to the Great Wall, a length of 700 miles, and ranging in breadth from 100 to 150 and 300 miles. Though part of this great plain is soft and marshy, yet, upon the whole, it is in a high state of cultivation and fertility, yielding rice, wheat, sugar, cotton, tobacco, and other produce.

4. *Southern Asia*, including Hindoostan, or India within the Ganges; and Birmah, Siam, Laos, Annam, and Malaya, or India without the Ganges. This is decidedly the finest region of Asia, is diversified by minor hill-ranges and well-watered valleys, enjoys a high, though not an oppressive temperature, has only a rainy season for its winter, and except during long droughts, presents in every district an unfauling verdure. India without the Ganges consists of a curious alternation of parallel ridges and valleys—the former rising to no great height, unless in the north; and the latter rather narrow, but of great fertility, though liable to inundations during the rainy season. India within the Ganges exhibits greater diversity: the plains of the Indus and Ganges (including the *Punjab*, or district between the five tributaries of the former, and the *sunderbunds*, or alluvial delta of the latter) exhibit well-marked features of tropical verdure and fertility; but there are also large sandy or gravelly deserts between those plains doomed to utter barrenness. South of those plains the country becomes hilly, and passes in the Deccan, or peninsular part, into a high dry table-land, fenced by the Eastern and Western Ghauts, and rendered irregular in surface by the Nilgherry and other hills.

5. *Western Asia*, which, with a few minor exceptions, may be said to consist of high sandy plains, studded with salt lakes, very inadequately watered by rivers, and, on the whole, a hot and arid region. It embraces Arabia, Turkey, Persia, Beloochistan, Afghanistan, and South-Western Tartary; the minor exceptions to the general character being the hilly districts of Afghanistan, Georgia, and Western Turkey. The desert steppe of Western Tartary is of no great elevation, skirts the whole of the Caspian, and passes insensibly into that sandy tract already described under Russia in Europe, p. 208. The table-land, or rather table-lands of Persia, are of varied character—high (5000 feet), rugged, and cold in the north-east; descending to 3000 feet a little farther south; and in the central

and southern parts spreading out into sandy, gravelly plains, from 1200 to 2000 feet high, only partially intersected by narrow valleys in the west, and stretching into the arid moving deserts of Beloochistan in the east. Turkey is more diversified than any other part of Western Asia; has several high ranges, the peaks of which are above the snow-line; a number of fertile valleys; a few rather bleak and elevated table-lands; some sandy and brackish tracts in the south; and the large low alluvial valley of the Tigris and Euphrates in the south-east. Arabia is altogether a high isolated table-land, consisting principally of arid, sandy desert, interspersed with hilly ridges and narrow shrubby valleys—unknown to all save the wandering tribes, who find a scanty subsistence on its plains.

#### GEOLOGICAL STRUCTURE.

The geology of Asia is very imperfectly known: nothing like a general sketch of the succession and relation of its formations has been, or indeed can yet be, attempted. All that we know for certain is, that most of its great plains are of very recent formation; that active volcanoes are still within its limits; that its tertiary and post-tertiary deposits have, at no very distant date, been subjected to volcanic forces; and that almost all the older formations have been noticed at isolated points by successive travellers. Thus the great plain of Siberia consists of post-tertiary clays, gravels, and sands, in which the remains of elephants, rhinoceroses, and other huge animals, no longer existing there, are found in abundance; the great plain of China is strictly alluvial, and still in course of formation; so likewise are those of the Ganges and Indus; and the sandy tracts of Arabia and the west, with their petrified woods and nummulite limestones, point to a comparatively recent elevation from the waters of the ocean. The depressions of the Dead Sea, Caspian, Cutch, &c. point also to recent geological changes; while the mountain-ranges and table-lands—already described under PHYSICAL GEOGRAPHY, vol. i., p. 57—seem to have been cold and permanent for ages.

Economically, *coal* is found in the north of China, in Syria, and in Hindoostan; *salt* in China, Hindoostan, West Siberia, Persia, Arabia, and Turkey; *marble* in Turkey; *asphalte* in Syria, Persia, and the Caspian; *gold* in Japan, China, west borders of Siberia, Birmah, and the Malayan Peninsula; *silver* in China, Japan, West Siberia, and Turkey; *tin* in China, Birmah, Siam, and the Malayan Peninsula; *quicksilver* in China, Thibet, Japan, Hindoostan, and Ceylon; *copper* in Japan, West Siberia, Thibet, Turkey, India, and Persia; *iron* in the Oural, India, China, Siam, Japan, Turkey, Persia, and Afghanistan; *lead* in China, the Oural, Turkey, Georgia, Persia, Siam, and Japan; and *precious stones*, including the diamond, in India, the Oural, Chinese Empire, and Persia.

#### HYDROGRAPHY, &c.

The *seas, bays, and gulfs* which indent and intersect the surface of Asia are in many respects peculiar, but in noway so remarkable as those which give character to Europe. On the *north* the Gulf of Obi, a large shallow basin, for ten months in the year covered with ice, is the only important inlet. On the *east* the large and little-known sea of Okhotsk; the island-surrounded Sea of Japan, with its volcanic coasts; the basin of the Yellow Sea, and its subordinate Gulf of Petchili, so shallow, that there is scarcely six fathoms of water 100 miles off shore; the Gulfs of Tonquin and Siam. On the *south* the Gulf of Martaban; the large open Bay of Bengal, terminating in the numerous navigable mouths of the Ganges; the Persian Gulf, celebrated for its pearl fisheries, about 550 miles long, and 150 in breadth, connected with the Gulf of Oman by a strait 30 miles across; the Red Sea, with its numerous islets and reefs, 1420 miles long, average breadth 135—terminating in the small Gulfs of Suez and Akaba; the former 180 miles by 22, the latter about 120 by 13.

The principal *straits* are those of Bab-el-Mandeb,

forming the entrance to the Red Sea, less than 20 miles across; Palk's Strait, between Ceylon and the mainland of Hindoostan; Straits of Malacca, forming the highway between the Indian and Chinese Seas, about 520 miles long, and from 25 to 180 broad; the Channels of Fokien and Formosa, on either side of that island; the Straits of Corea and La Perouse, running between Japan and the mainland of the continent; and Behring's Straits, separating Asia from America, at its narrowest part not exceeding 36 miles.

The islands more immediately connected with Asia are the Liakhov group in the Arctic Ocean; the Aleutians in the Sea of Kamtchatka; the islands of Japan; Saghalien, Formosa, Hainan, and Chusan off the coast of China; Ceylon, the Andaman and Nicobar Isles in the Indian Ocean; and Cyprus in the Levant. The Japan Isles, forming the empire of that name, consist of Nippon, Yezo, Kiusiu, Sikoke, and the Kuriles, altogether occupying an area of 266,600 square miles, of volcanic origin, subject to destructive earthquakes, of average fertility, rich in minerals, and peopled by a busy and ingenious people. The fine island of Ceylon, now a free colony, has an area of 24,500 square miles, and whether as regards its vegetable, animal, or mineral produce, is one of the most valuable of the British possessions. [The large islands of Sumatra, Java, Borneo, Celebes, &c. generally known as the East India Islands, are treated under the head MALAYIA in a subsequent number—68, p. 281.]

The lakes or inland seas of Asia constitute one of its peculiar features, most of these being salt or brackish, having no visible outlet, and in some instances considerably beneath the general level of the ocean. The largest of these is the Caspian, having a length of 760 miles, with an average breadth of 200, receiving the rivers Wolga and Oural, but with no outlet; its waters brackish, and of unknown depth, and its surface-level fully 116 feet beneath that of the Black Sea. Next is the Sea of Aral, about one-fifth of the size of the Caspian, with brackish or bitter water, receiving the streams of the Jyhoun and Sihon, but having no river of discharge. Of the same character are the smaller lakes Tenghiz, Khasselbach, Oubsa, Koko, Bosteng, &c.—all in the high central plateaux; and Van, Ourumia, Koch-Hissar, the Dead Sea, and others in West Asia—the last being not less than 1312 feet beneath the level of the Mediterranean. Of fresh-water lakes with outlets, the principal are Baikal in Siberia, 400 miles long, and from 40 to 60 broad, abounding in seals and fish; Tchang, formed by the Irtish; Erivan in Armenia; Tongting, Poyang, and Hai in China; and Tabaria in Syria, 328 feet beneath the Mediterranean.

Of the rivers which water the continent, a large number are of the first class; and others, though of minor volume, become interesting from their historical associations. The bleak regions of the north are traversed by the Obi, with its large tributaries Irtish and Tobol, by the Yenesei, the Lena, and Indigirka—all of which fall into the Arctic Ocean, and, from being frozen for so many months, are of little use to internal communication. In Eastern Asia we find the Amour, Hoang-ho, Yang-tee-kiang, and Hong-kiang, all of which are slow flowing rivers, and navigable for a long way into the interior. India without the Ganges is watered by the rapid but little-known rivers Camboja, Meinam, Thalesin, and Irawady; and Hindoostan by the Brahmapoutra, the 'sacred' Ganges, and not less celebrated Indus, with its classical tributaries Sutluj, Ravee, Chenab, and Jelum. The Ganges, though subject to annual inundations, and to a very rapid and dangerous tidal bore, is one of the most valuable rivers in the world, being, with most of its tributaries, navigable to the very basis of the mountains. The same, however, cannot be said of the Indus, which, though of ample volume, has an obstructive and shifting delta, which renders it of little avail, unless to small steamers. In Western Asia are the Tigris and Euphrates—the latter, as has been recently proved, navigable for flat-bottomed steamers so high as Bir.

The climatic effects have been already adverted to, in a general way, under the description of the respective regions; but there are certain specialities which require consideration. As a whole, the continent of Asia does not enjoy the same modifying and mollifying influences as Europe. A large proportion is situated on the confines of the Polar Circle; a still larger section raised to an enormous altitude: it lies comparatively unbroken by intersecting seas; it has no burning sandy tracts on the south to send warm breezes, as Africa does, to Europe; while even its southern tropical districts are cooled by currents from the snow-clad central plateaux. It therefore suffers what Humboldt calls an *excessive* climate—that is, excessively hot in summer, and excessively cold in winter, or differing greatly during these seasons from the mean annual temperature. Thus excellent grapes come to maturity on the borders of the Caspian, and yet the thermometer in winter falls to  $-28^{\circ}$  Fahrenheit. At Tara in Siberia the temperature of the air in July and August rises to  $82^{\circ}$ , and yet a few inches under the surface the soil remains perpetually frozen. The snow-line in the Elburz is found at 11,000 feet, on the south side of the Himalaya at 12,000 feet, and yet in Thibet the mountains are clear at an elevation of 16,000 feet. In Arabia, after a night of hoar-frost, the day-heat is often as high as  $114^{\circ}$ . At Bombay the mean annual temperature for 1844 was  $81\frac{1}{2}^{\circ}$ —being in January  $76^{\circ}$ , February  $76^{\circ}$ , March  $79\frac{1}{2}^{\circ}$ , April  $84^{\circ}$ , May  $86^{\circ}$ , June  $85\frac{1}{2}^{\circ}$ , July  $82^{\circ}$ , August  $81\frac{1}{2}^{\circ}$ , September  $80\frac{1}{2}^{\circ}$ , October  $83\frac{1}{2}^{\circ}$ , November  $80\frac{1}{2}^{\circ}$ , and December  $79\frac{1}{2}^{\circ}$ ; the greatest cold experienced being  $55\frac{1}{2}^{\circ}$  in January, and the greatest heat  $92\frac{1}{2}^{\circ}$  in May. The wet season in the same year—that is, June, July, August, and part of September—yielded, by rain-gauge, upwards of 66 inches of rain.

BOTANY AND ZOOLOGY.

The vegetation of Asia, as might be expected from its varied climate, soil, altitude, and other physical causes, is more abundant and diversified than that of any other region. The general features have been already adverted to under the different regions into which we divided the continent; but in addition to these we may notice the following as more especially characteristic:—Of forest trees—the teak, cedar, sycamore, cypress, savin, mangrove, bamboo, banyan, plantain, cocoa, and a variety of other palms, besides aloes, ebony, iron-wood, rosewood, sandalwood, and other ornamental hardwoods. Of fruits—the grape, orange, shaddock, lemon, lime, tamarind, mangosteen, mulberry, olive, pomegranate, walnut, almond, cocoa, bread-fruit, cashew, betel, banana, pine-apple, melon, quince, date, apricot, and all the garden fruits known in Europe. Of spices and kindred trees and shrubs—cinnamon, nutmeg, clove, camphor, cassava, tea, coffee, cotton, sugar-cane, sago-palm, &c. Of grains, cultivated roots, &c.—rice, wheat, dhourra, maize, barley, pease, beans, lentils, and other leguminosae; potato, yam, lotus, arrowroot: of plants yielding drugs and dye-stuffs—indigo, arnatto, saffron, gamboge, galls, poppy, rhubarb, castor-oil, sarsaparilla, ginseng, and many others.

Of the animals characteristic of Asia, we may enumerate among the *mammalia*—the apes and monkeys of the south; the elephant and rhinoceros of India; the lion, tiger, leopard, panther, ounce, and other felinae in the south and west; the wolf, jackal, blue and black fox, and numerous varieties of the dog; the horse, ass, and dziggetai of Arabia; the common ox, buffalo, auroch, yak, and musk ox; the elk, reindeer, axis, argali of Siberia, Angora goat, ibex, moufflon, and fat-tailed sheep; porcupine, jerboa, curious bats, marmot, lemming, beaver, ermine, &c.; bears, badgers, gluttons, sea-otters, seals, mooses, manati, and other cetacea. Among *birds*—the peacock, pheasant, white partridge, and innumerable pigeons; eagle, vulture, falcon; parrots, paroquets, macaws, &c.; stork, heron, cormorant, pelican; birds of paradise, and others of gay

plumage; but very few songsters. *Reptiles*—alligators in the Indian rivers; boa constrictor, python, and a number of deadly serpents in the jungle; edible turtle; lizards, toads, and frogs. *Fish*, of every kind and hue, in all the rivers, lakes, and seas, including sharks, sturgeons, flying-fish, &c.; *shells* of the rarest beauty and elegance; and *insects* in innumerable species—some useful, as the silkworm, bee, and those producing cochineal, gall-nuts, lac, &c.; and others destructive and poisonous, as the locust, scorpion, and mosquito.

POPULATION—INDUSTRY, &c.

The *inhabitants*, usually estimated at 400,000,000, belong to the three great varieties—Caucasian, Mongolian, and Malay; but these, in the course of time, have broken into a number of distinct families, races, and tribes, which are extremely puzzling to the ethnologist. Without attempting any formal division, the *first* variety may be regarded as including the Circassians, Georgians, Armenians, Syrians, Arabs, Persians, Afghans, and Hindoos in the west and south; the *second*, the Tartars, Turks, Kalmucks, Mongols, Thibetans, Mandchoos, Japanese, Chinese, Birmese, and others of the central and eastern countries; and the *third*, the Malays, Macassars, &c. chiefly in the south-eastern peninsula. Or, more generally still, the Hindoos, Chinese, Tartars, Arabs and Persians, may be said to divide among them the continent as an inheritance, giving to it languages, religions, laws, customs, and civilisation. Besides the Asiatics Proper, there are a considerable number of Europeans located in different countries—as Russians in Siberia, Greeks in Turkey, British, French, Portuguese, and Danes in India. The prevalent *religious* creeds are—Mohammedanism in Turkey, Arabia, Persia, Afghanistan, Beloochistan, and parts of India; Brahminism and Bhuddism in India; Bhuddism in the Chinese Empire, Birmah, Siam, and the East; Idolatry or Fetichism in Eastern Siberia; and Christianity in several forms in Turkey, Western Siberia, and European India.

As regards *civilisation*, whatever may have been the condition of Syria, Persia, India, and other celebrated nations of antiquity, the continent of Asia is now, with a few fractional exceptions, in a state of semi-barbarism and stagnant imbecility. Siberia has yet reaped little from Russian influence, and is for the most part physically incapable of doing so: Tartary, Thibet, Mongolia, and the whole of Central Asia, are occupied by nomadic races, whose flocks and herds constitute their sole wealth and subsistence; China and Japan, though possessing a literature, laws, and religion, though their people dwell in cities, cultivate the soil with exactitude and care, and exhibit considerable skill in the domestic arts, are little, if anything, in advance of what they were several centuries ago, being destitute of that elasticity and adaptive capacity essential to a progressive civilisation; India without the Ganges is still far from being entitled to be ranked with civilised nations; Hindoostan, with its numerous races, and once independent states, is morally and industrially, as well as politically, dead—all that British influence has yet effected being trifling in comparison with the field before it; the Afghans and Beloochees are rude, half-pastoral, half-agricultural, warlike races, only as yet in the second stage of civilised existence; Arabia and Persia have been dormant, if not retrograding, for centuries; and even Turkey, with its fertile soil, fine climate, and varied produce, is by no means entitled to be ranked with the European section of the empire of which it forms a part.

The *industrial* and *commercial pursuits* of a continent so little advanced in civilisation must necessarily be of a humble and limited description—directed more to the rearing and collecting of raw produce for export, than to the arts and manufactures. Mining constitutes the chief industrial feature in Western Siberia; the Chinese rear tea, cotton, silk, and rice, manufacture silk and cotton stuffs, porcelain, firearms, gunpowder, books, and toys, and carry on a considerable coasting

trade;\* the Japanese are celebrated for their lackered wares; India for her silk, cotton, rice, indigo, opium, coffee, and other raw produce, her bandanas, crape shawls, and similar manufactures in silk; Cashmere for its exquisite shawls; Persia for carpets; Arabia for its coffee and spices; Turkey chiefly for her abundant and varied raw products, and in less degree for her sword blades, damask silks, and interior caravan commerce.

COUNTRIES AND GOVERNMENTS.

The native governments of Asia are generally despotic, tempered, however, by their religious creeds and patriarchal customs. The political divisions are exceedingly unstable; for which reason we merely exhibit the countries, with their areas, population, and chief towns, devoting the remainder of our sheet to an account of the East Indies, that section of Asia in which the British reader is more especially interested:—

Countries.	Sq. Miles.	Population.	Chief Towns.
Siberia, - - -	5,200,000	7,000,000	Tobolok.
Chinese Empire,	5,400,000	184,000,000	Pekin.
Japan, - - -	120,000	12,000,000	Jedo.
Tartary, - - -	750,000	7,000,000	Turkestan.
Turkey, - - -	460,000	13,000,000	Smyrna.
Arabia, - - -	1,000,000	10,000,000	Mecca.
Persia, &c. - -	510,000	13,000,000	Teheran.
Afghanistan, -	250,000	5,500,000	Cabul.
Beloochistan, -	200,000	5,000,000	Kelat.
Hindoostan, - -	1,250,000	121,500,000	Calcutta.
Farther India,	903,000	21,000,000	Amarapoura.
Total, - - -	16,062,000	399,000,000	

The European powers having possessions in Asia are—*Russia*, occupying the whole of Siberia, partly as a mineral and trading region, and partly as a penal settlement: *Britain*, which has acquired the ascendancy, if not the actual possession, of the most of Hindoostan, Ceylon, Assam, Chittagong, various settlements on the Birmese and Malayan coasts, the valuable little island of Singapore in the Straits of Malacca, the islet of Hong Kong at the mouth of the Canton river in China, and the rocky peninsula of Aden in Arabia: *France*, which owns the small districts or factories of Pondicherry, Villenour, Chandernagore, Gonjam, Carical, Mahé, &c. on the coasts of Hindoostan: *Portugal*, which still possesses the maritime districts of Damaun, Diu, Goa, and Margaon: and *Denmark*, which, since the British purchase of Serampore in 1846, has only the small territory and seaport of Tranquebar in the Carnatic.

*Note*.—The following descriptive words are of frequent occurrence:—In China the termination *foo* denotes a town of the first class; *tschou*, one of the second; *hien*, one of the third; *hou*, lake; *ho*, river; *kiang*, river; *keou*, mouth. In Hindoostan—*abad*, dwelling or city; *poor*, pore, puram, town; *palam*, town; *droog*, fort; *gur*, *ghur*, castle; *bazar*, market-place; *cherry*, city; *nagore*, *nuggur*, town; *serai*, inn; *oot*, *colla*, fort; *sear*, *searra*, region; *slan*, a country; *giri*, mountain; *gherry*, hill; *ghaut*, mountain-pass; *ab*, *aub*, water or river; *feet*, shallow lake; *maha*, great; *nih*, blue; *diva*, *divc*, island. In Persia and Arabia—*jebel*, hill; *nahar*, river; *ras*, cape; *hissar*, fortress; *meshed*, mosque; *deh*, village; *harr*, castle; *gherd*, fortress; *koh*, mountain-peak; *bostan*, garden; *tagh*, *dagh*, mountain. In Palestine—*ain*, en, fountain; *baal*, temple; *bahr*, sea or lake; *beth*, house or dwelling; *kirjath*, city; *ramah*, high ground; *weady*, valley. In Turkey—*dagh*, *tagh*, mountain; *koom*, desert; *denghis*, *dengis*, lake; *chai*, river; *pol*, *poli*, city; *grad*, *grade*, fortress; *shahr*, town; *serai*, palace; *keissas*, *keitsch*, church; *khan*, inn; *hissar*, castle; *ko*, *koi*, village; *bazaar*, *bazar*, market; *ezki*, old; *novi*, new; *gend*, young; *bala*, upper; *buyuck*, great; *jih*, *kuichuk*, little; *ak*, white; *kara*, black; *kisil*, red.

\* The superior industry of the Chinese, as compared with other Asiatic nations, is proved by their extensive exportation of manufactured articles. To those above enumerated we may add—alum, white and red lead, brass leaf, zinc, glass-beads, paper-hangings, table and floor mats, &c. Besides exporting native productions, China is also an entrepôt for those of the adjacent countries, and occasionally even for those of Europe.

## EAST INDIES.

India, Hindoostan, or the East Indies, as it is called, southward to the Indian Ocean. It is nearly comprehended between the latitudes of 8° and 35° north; its extreme length from north to south is about 1900 miles, and from east to west about 1500; its superficial area

measures 1,260,000 miles. The northern boundary of this extensive region is formed by the Himalaya Mountains, so called from an Indian word signifying snow—their peaks, at an elevation of 16,000 feet or thereby, being perpetually clothed with ice and snows. From the extremities of this mountain-chain flow two large rivers, which form on either side the boundary of

India; that on the east is called the Burhampooter or Brahmapoutra, and that on the west the Indus—a river from whose name the whole country has derived its present designation. Each of these streams, with its tributaries, water an immense tract of fertile country, and afford excellent means of internal trade to the people situated on the banks. From the mouths of

these rivers the coast stretches both ways to the southward, the eastern and western side inclining to the same point, so as to meet at Cape Comorin. Beyond this, the adjacent island of Ceylon extends a little farther, and reaches to within about 6° of the equator.

This extensive country presents, as already stated, a great variety of surface, being diversified in some places with wide sandy deserts; in others with fine undulating hill countries, well watered and fertile; a third portion consists of flat high-lying regions, called table-lands, which, from their height above the sea, are cool and temperate; and a fourth division consists of immense fertile plains, watered by the large rivers of the country, and their numerous tributaries. A considerable portion of the low-lying country is of a marshy shrubby character, called jungle, and unfitted for cultivation. Each of these divisions of India presents an aspect peculiar to itself, and all of them are distinguished by natural productions, both plants and animals. Besides the Indus on the west, and the Brahmepoutra on the east, there are other large and important rivers descending from the outskirts of the Himalaya Mountains, or from ranges of hills called Ghauts, and descending to the sea both on the east and west coasts. The principal of these streams is the Ganges, which, with its tributaries, drains a large portion of the north-east division of the country, and enters the sea in the province of Bengal, along with the conjoined waters of the Brahmepoutra. The valley or plain of the Ganges, and the valleys of its confluent, form the fairest and richest portion of Hindoostan.

**Territorial Divisions.**

The modern territorial and political subdivisions of India, though of little practical moment, may thus be specified:—First, **NORTHERN HINDOOSTAN**, an extensive and rugged territory, comprehending—

- |   |                        |
|---|------------------------|
| 1. The country between the<br>Sutluj and Jumna. | 4. Kemacon.            |
| 2. Gurwal or Serinagur.                         | 5. Patnkhandi.         |
| 3. Sources of the Ganges.                       | 6. Bootan.             |
|   | 7. Dominions of Nepal. |

Second, **HINDOOSTAN PROPER**, which is the most comprehensive division. It stretches across the centre of India, and obtains the most prominent place in the history of the old Mohammedan empires of India. It reaches south to the Nerbudda, where the Deccan commences, and includes the following provinces:—

- |               |              |                        |
|---------------|--------------|------------------------|
| 1. Bengal.    | 5. Agra.     | 9. Ajmeer.             |
| 2. Bahar.     | 6. Delhi.    | 10. Moutan.            |
| 3. Allahabad. | 7. Lahore.   | 11. Cutch and Guzerat. |
| 4. Oude.      | 8. Cashmere. | 12. Malwa.             |

Third, **THE DECCAN**.—This division lies next, in a southerly direction, to the above, extending from the Nerbudda river on the north, which flows into the sea on the west coast, to the Kistna, a river flowing into the sea or Bay of Bengal on the east coast. Between these rivers lies the Deccan, a much less fertile division of India than the preceding; Bombay, a small island on the west coast, belongs to the province of Aurungabad in this division. The Deccan comprehends the following provinces, a portion of which formed the once famous **Mahratta** empire:—

- |                          |             |                |
|--------------------------|-------------|----------------|
| 1. Gundwana.             | 4. Candesh. | 7. Hyderabad.  |
| 2. Orissa.               | 5. Berar.   | 8. Aurungabad. |
| 3. The Northern Circars. | 6. Beeder.  | 9. Bejapore.   |

Fourth, **INDIA, SOUTH OF THE KISTNA**.—This division forms the extreme southerly portion of the Indian peninsula, and comprehends the provinces of—

- |                                |  |
|--------------------------------|--|
| 1. Canara.                     | 6. Mysore.                                       |
| 2. Malabar.                    | 7. Colmbatoor.                                   |
| 3. Cochin.                     | 8. Salem, and the Barramahal.                    |
| 4. Travancore.                 | 9. The Carnatic, in which is<br>situated Madras. |
| 5. Balaghaut, ceded districts. |  |

In addition to the foregoing divisions and provinces,

the large territories of Ava and the Burmese empire, lying east from the Brahmepoutra, are now attached to India, besides other conterminous regions.

It is customary to speak of the preceding provinces and states as British, Tributary, or Protected and Independent, but such a distinction is upon the whole rather nominal than real. British influence now pervades the whole region, from the Himalayas to Cape Comorin on the one hand, and from the Indus to the Ganges on the other; and as for any individual or separate power which the Protected States can exercise, they might as well be termed British, while the really Independent territories, as Scindia, Nepal, and the Punjab, are gradually being reduced under British sway. How little of Hindoostan, territorially speaking, does not now acknowledge the supremacy of British power, may be seen at a glance by referring to any coloured map of the country.

**Modern History.**

What was the original political condition of the vast territory now composing the British Indian empire, it would be needless to detail minutely. Like other portions of Asia, it was early inhabited by a primitive people, more or less barbarous, professing different pagan religions, and speaking many more different languages. The principal religion, however, was Hindooism, to which we shall afterwards allude; and it has been said by some historians that the early Hindoo race of inhabitants manifested many symptoms of civilisation, and even a knowledge of some of the sciences. However this may have been, the inhabitants generally were in some measure an industrious, but simple race, and little inclined to war. Reasoning from what has occurred in their history, as well as from the information communicated regarding them, they seem, from the earliest times, to have had little or no care with regard to who ruled over them, provided they were insured in the possession of their ancient religious usages, and their system of living in small communities, under a simple species of local government. They were reckless of what sovereign was placed over them, or to what dynasty they were transferred, so long as the internal economy of their village districts remained the same. This species of political apathy produced the results which might have been expected. From the most remote period of which any record is preserved, the inhabitants of India, including those tribes which possessed more decided warlike propensities, or who had the spirit to resist aggression, were subjected to the government of strangers, who seized upon their territories, and made them the objects of taxation.

Of the remoter period of Indian history little is correctly known; all that may be said of it is, that both the Greeks and Romans were supplied with some of their articles of luxury from Hindoostan, and that for many centuries this Eastern clime was supposed, by the ill-informed inhabitants of distant parts of Asia and Europe, to be the richest and most sumptuous country on the globe. The tales related of Indian grandeur appear to have in time excited the avarice and ambition of Mohammedan or Saracen chiefs. The first of this barbarous, though intrepid race who made a successful inroad upon India was Mahmoud, sultan of Ghuznee, or Afghanistan, a kingdom on the north-west of India. Mahmoud commenced his successful expeditions into India about the year 1000, and he continued them till 1024, making the destruction of pagan idolatry more the object of his visits than the acquisition of wealth or power. In this period of twenty-four years he had subdued a considerable number of the native princes, and notwithstanding his professions, exacted immense tributes in gold and every kind of valuable commodity. A successor of Mahmoud, named Mohammed, after carrying on war with the Indian princes for some time, at length, about the year 1193, entered Hindoostan with an exceedingly large force, and bore down all opposition. The king of Delhi was slain in battle, and having advanced to that ancient capital,

## EAST INDIES.

Mohammed there left a viceroy to maintain his authority. In this manner a Mohammedan dominion was for the first time established in the heart of India, and in one of its greatest cities; and thus commenced the Afghan or Patan sovereigns and their dynasty.

The dynasty so planted continued in existence for rather more than 800 years, when, in 1525 or 1526, it was subverted by Baber, who was considered one of the most adventurous warriors of his time, and who, like his prototype Mohammed, was of the Moslem faith. Baber was either descended from a Mogul or Tartar chief, or in some way, not clearly explained by historians, connected with a race called Megula, who assisted him in his attempts upon India; and from cause of this nature, the empire which he founded in Hindoostan has ever since been called the Mogul empire. From the year 1526, a series of Mohammedan emperors, whose seat of authority was at Delhi, ruled the largest and finest portions of India. By them the country was in many places newly subdivided into provinces, and put under the government of tributary kings or nabobs, who superseded the Hindoo rajahs or petty princes. One of the greatest of these Mogul emperors was Akbar, who flourished between the years 1556 and 1605. By his daring and judicious management the central provinces were preserved in complete tranquillity, and Guzerat, Bengal, and part of the Deccan, were added to his already extensive empire.

While the emperors of India were thus establishing their power, multifarious schemes were formed in Europe for getting possession of some of the wealth, if not some portions of the territory, of Hindoostan. The commodities of Indian manufacture or produce were hitherto imported into the European states only by means of tedious overland journeys, or partly by the Red Sea, and were endangered in their passage by the attacks of ferocious Tartar and Turkish tribes. The discovery of a new and safe road to India thus became a matter of very great consequence. A route by sea round the Cape of Good Hope was at last found by the Portuguese, who, under the command of Vasco de Gama, in 1498, landed in Hindoostan, on the coast of Malabar, where they at once established themselves. The whole commerce of the East Indies was now in the hands of the Portuguese for nearly a century—and this was the golden age of Portugal. Lisbon became the great depôt of Indian spices and other commodities, greatly to the envy of the Dutch and other nations. Portugal was united to Spain in 1580; the Spaniards oppressed Holland, and caused it to revolt; this revolt was followed by the capture of the Dutch ships trading to Lisbon; and this capture compelled the Dutch to engage in a direct trade to India. The English soon followed their example. The political and spiritual tyranny of the Portuguese in India, as well as the abuses which they permitted in commerce, gradually subverted their power, and divested them of respect. The Dutch and English, therefore, found everything in that state of division which is favourable to the establishment of a third party. The Dutch established an East India Company in 1602, and a prosperous trade was thereafter carried on. The Dutch adopted quite a different line of policy from that of the Portuguese in their transactions with India. They cared nothing about the religion of the Hindoos, and set up no inquisition to force Christianity on those they dealt with; all they wanted was commercial intercourse, and their excellent management soon secured them a large share of the Indian traffic. They possessed themselves of Batavia, in the island of Java; in 1641 they acquired Malacca, the capital of the Portuguese East Indies; they subsequently acquired the Cape of Good Hope for a settlement; and these colonies were a great assistance to the intercourse between Europe and India. The Dutch subsequently acquired a number of other possessions in the East; but most of these came afterwards into the possession of the British.

We now enter upon the history of the rise and progress of the British power in India. The English

became animated with a desire to open a commercial intercourse with India as early as the reign of Edward VI. (1553); but their expeditions failed in reaching the desired country, from their want of geographical knowledge: and it was not till the shutting of Lisbon against the Dutch, that they were so far excited as to persevere in their maritime attempts till they were successful. They at length learned which was the true course to steer for India; whereupon, in 1600, a company of merchants was formed in London to prosecute the traffic with the East; being empowered to do so by a charter from Queen Elizabeth, which was to last fifteen years. The first expedition of these adventurers cost £69,091, and consisted of five ships, the largest of which was 600, and the smallest 130 tons burthen. The articles which they took were principally bullion, iron, tin, broadcloths, cutlery, and glass. This expedition proved remarkably successful, and led immediately to a repetition of annual voyages of the same nature. This early trade was nevertheless considerably hampered by the Portuguese; and it was found necessary to try to secure the favour of the Mogul emperor. In 1607, therefore, Captain William Hawkins was sent out by the Company, to endeavour, if possible, to open a commercial intercourse with the dominions of the Mogul. Hawkins, after surmounting great difficulties, placed in his way by the Portuguese, reached the court of the Mogul emperor Jehangire, son of the famous Akbar, already mentioned. This visit was unfortunately of no avail, from the pernicious interference of the Portuguese Jesuits; and another English mission, on a greater scale, and from the king, was sent forth in 1615. This embassy, which was conducted by Sir Thomas Roe, proved more successful in securing the favour of the Mogul, but did not lead to any important results. The affairs of the Company, nevertheless, continued prosperous, and factories were in many places planted on the coasts of India. These factories were warehouses for the reception of native produce, and the storing of imported goods from England, and were no doubt of considerable use in the objects of their establishment. From the real or pretended dread of being attacked by marauders, the keepers, merchants, and servants at these places, at length began to strengthen the defences; and so, from being mere mercantile warehouses, the factories shortly partook of the decided character of armed garrisons.

It does not appear that the native powers of India took any active measures to prevent this insidious process of planting settlements. The natives were fond of dealing with foreigners, and the princes were so eaten up with jealousy of each other, that the British always contrived to gain the friendship of one by taking part against another, and in the end getting the advantage of both. Besides, it was not for some time that the British disclosed any intention of securing the jurisdiction of provinces, or a property in the soil. A watchful hypocrisy led them to yield on all occasions a reverence towards the political sway of the native emperors, rajahs, and nabobs. The original East India Company, with its charters at different times disputed and renewed, continued throughout the seventeenth century to carry on a profitable traffic with the East. Its factories were extended to Java, Sumatra, Borneo, the Banda Islands, Celebes, Malacca, Siam, the coasts of Malabar and Coromandel. In 1640, the native authorities gave permission for the building of Fort St George at Madras; and in 1645, a factory was established on the banks of the Hoogly, a branch of the Ganges near its mouth, which formed the foundation of Calcutta. The island of Bombay was also procured as a settlement in 1664-5, after a struggle with its Portuguese possessors. The affairs of the Company were not, however, in a prosperous state; and soon after the Revolution of 1688, the question of the validity of the old royal charter was started. The consequence followed of the Company not being able to perform its obligations, on account of losses occasioned by wars, infidelity of officers, extravagance, &c.; and

parliament in 1698 granted a charter to a new East India Company, on condition of a loan of £2,000,000 sterling to the state, and which was required to carry on King William's wars. But the great contentions between the two Companies soon made it necessary to unite them, and a union was effected in 1702, when an act of parliament was passed, establishing the conjoined association under the title of the United Company of Merchants trading to the East Indies. Stock was raised by the sale of shares, and the shareholders to a certain amount were entitled to elect directors.

The progress of the Company's settlements in India was on several occasions about this period caused by the superior skill of the British in medicine. In 1715, an embassy being sent on a commercial commission to Delhi, it happened that a medical gentleman named Hamilton, who accompanied the factors, had the good fortune to cure the Emperor Ferokszere of a severe illness, which could not be overcome by the ignorant native physicians. In gratitude for this important service—though, it is likely, some very valuable presents from the Company had an equally liberalizing effect—the emperor granted liberty to the Company to purchase in Bengal thirty-seven townships in addition to that of Calcutta; he also conferred upon them some important commercial privileges, which soon rendered Calcutta a flourishing settlement. The charter of the East India Company was from time to time renewed during the eighteenth century, though (but not without great difficulty) against a powerful opposition. But loans to government carried them always through these embarrassments. In 1744 they advanced £1,000,000 at 3 per cent., in consideration of an extension of their privileges till 1780. Hitherto we have seen this company of English merchants acting only for the avowed object of commercial intercourse with India; we now enter upon a new page in their history, and show the origin of their political power.

The East India Company assumed the qualifications of a military and political power in the year 1748. But their advances towards territorial dominion were retarded by a rival, which gave them no small trouble. This competitor was France, which had in the meantime hastened to share in the commerce and spoils of India. In 1746, a French battalion had destroyed the army of the nabob of the Carnatic, and soon after the French officers succeeded in disciplining Indian troops according to the European method. The inferiority of the native Indian troops opposed to European soldiers, and the facility of instructing Indian soldiers, known by the name of *Sepoys*, in the European tactics, was thus proved. Ambition and avarice, political and mercantile cunning, could now act on a larger scale; and the independence of the Indian princes was gone whenever this trading Company, which was already encroaching upon all the rights both of the rulers and the people of these countries, should establish a permanent military force. Thus far the military organisation of the Company had been merely on the defensive; it now became able to act offensively; and the entire difference of the European and Indian notions of law could never fail to furnish opportunities to put this new means of power into action. The rights of succession, and all the rights of princes, subjects, and families, were so much disputed on the different principles of the Indian, Mohammedan, and British laws, that the Company, which often interfered as arbitrator, easily succeeded in extending their legal jurisdiction. If called to account in England for any of its undertakings, it was easy to uphold the correctness of its conduct, politically, on the ground of self-defence, which, at the distance of several thousand miles, could not be called in question; and in legal matters, by taking advantage of the impenetrable labyrinth of the law. Edmund Burke, who experienced, in the case of Warren Hastings, the head of the Company's affairs in the East, this impregnability of the association, accused them justly 'of having sold every monarch, prince, and state in India, broken every contract, and ruined every state

who had trusted them.' In 1749, the robberies of the Company began with the protection of the pretender of Tanjore, a fine province of the Carnatic. Under pretence of illegitimacy, the nabob of this district was driven out for the purpose of obtaining some cessions of territory, and then restored on making further cessions. The rapid progress of the Company in the art of extending their possessions, appears from their treaties with Surajee-Dowlah, the nabob of Bengal whom they contrived to depose in 1757, when large and rich provinces were the reward of their faithless policy. The French, who, in a similar manner, had acquired considerable territorial possessions in the Carnatic, now came into collision with the British merchants, and a hot war was carried on in India between these contending Europeans. The indecency of this conflict, as to which party should be the greatest robber, seems to have shamed both France and England, and commissioners were mutually sent to India to reconcile the differences which existed, as well as to check the acquisition of territory either by the English or French Companies. As a matter of course, this affectation of justice ended in nothing. After the commissioners had agreed that each should restore its acquired territories, and after a 'solemn' treaty to that effect had been arranged, hostilities commenced as before. It would be needless to recount the particulars of this struggle for power; it will suffice to state that the French ultimately were deprived by the British of their possessions.

By the defeat of the French forces in 1761, the British were left at liberty to pursue their schemes on India, being in no small degree favoured by the unhappy political condition of the Mogul empire. This large empire came under the rule of Aurungzebe, a descendant of Akbar, in 1658, and his reign lasted till his death in 1707. Under this celebrated Mohammedan emperor, the empire of the Moguls came to the height of its glory, and attained its largest extent. After Aurungzebe had added to it the kingdoms of the Deccan, it included nearly the whole peninsula of Hindoostan, with the neighbouring regions of Cabool and Assam. The revenues extorted from this populous and wealthy territory amounted to £32,000,000 sterling. During the reign of Aurungzebe, it was attacked by the Persians under the bold Prince Nadir, and also by a growing nation called *Mahrattas*, whose kingdom comprehended large portions of the provinces of Malwa, Candeh, Aurungabad, and Bejapore, in the Deccan. By Nadir, and his successor, Ahmed Abdallah, the Mogul empire, after the death of Aurungzebe, was almost entirely subverted to the character of a tributary to the Persians. Under these circumstances, there was scarcely a native power that did not consider itself entitled to trample on the feeble authority of the throne of the Mogul; and between the Affghans, whose kingdom lay to the north-west, and the *Mahrattas*, the empire was distracted, and made the object of greedy contest. The Affghans were at length victorious over their enemy; and in 1753 they placed a descendant of the old dynasty on the throne, and in the possession of the empty, but still venerated title of Great Mogul, to be the tool or the captive of the first daring power which should seize the capital.

From this period the dignity of the empire was at an end, and a favourable opportunity was offered to the various dependent princes to throw off their allegiance, as well as to enterprising chiefs to take advantage of the unsettled state of things, and establish new kingdoms for themselves. In this state of general revolution, a bold Mohammedan adventurer arose from an obscure rank, named Hyder Ali, who, by summoning round him bold and predatory bands, and waging war with considerable address, established his power as a sovereign in the Mysore, a territory forming one of the most remarkable of those elevated table-lands that diversify the southern provinces. Hyder was succeeded in 1782 by his son Tippoo, a person equally bold, though less prudent and fortunate. Against both these powerful rulers the British for a number of years waged war with

various success. In 1792, Seringapatam, the capital of the Mysore, was besieged by the Marquis Cornwallis, with a strong British army, and after some show of resistance, Tipoo was fain to offer terms of surrender. He agreed to give up half of his dominions, and pay £3,500,000 in bullion. For the fulfilment of the treaty, he was under the necessity of giving up two of his sons as hostages. Having fulfilled his engagement, these young princes were returned in 1794; but after this he again commenced hostilities, and in 1799 the British forces, under General Baird, once more attacked, and now captured, Seringapatam. In the general slaughter which occurred in entering this strongly-fortified place, Tipoo was shot, and his body was afterwards found among a heap of the slain. Thus terminated a dynasty which, though short, and limited in respect of territorial dominion, was undoubtedly the most vigorous and best organised of any that had sprung out of the wreck of the Mogul empire. The principal war in which the East India Company was engaged after this successful contest was that with the Pindarees, roving tribes of Maharrattas, who, without any territory, carried on predatory warfare against all whom they could rob with impunity. The war with the Pindarees was one of great difficulty, and it cost the British a number of years before they finally quelled them. The Pindaree war terminated in 1817, and it was followed by a contest betwixt the British and the Birman empire, which was successfully closed in 1826, and by which the Company gained a considerable territory along the Bay of Bengal, east of the Brahmapoutra river. By the foregoing, and other less conspicuous contests with native princes, among which may be reckoned the war against the Nepaulese in 1814, and also by means of purchases, negotiations, and voluntary or involuntary renditions of territory, including the capture, cession by treaty, or purchase of the French and Dutch settlements, the British power was at length established as supreme over nearly the whole of India.

Hitherto the Company have governed their Indian territories by means of the presidencies of Calcutta, Madras, and Bombay, each of these places being the headquarters of a local military and civil government. In future there will be another presidency, that of Agra, a place of note in the interior. The whole are under the supreme control of a governor-general appointed by the British court; these governors-general seldom retain their situations above a few years. Mr Pitt, in 1784, passed an act establishing a Board of Control, composed of six privy-councillors, to superintend the territorial concerns of the Company, which check is still continued, and reappointed under the act of 1833. To retain possession of so large a territory as India, the Company require to keep up a numerous and well-appointed armed force, which is composed chiefly of natives or sepoy, with British officers, and partly of troops raised in Great Britain. The Company further employ a number of Queen's regiments, who have double pay allowed them. The army maintained in India consisted, in 1837, of 26,582 British, 157,753 native, and 111,500 contingent or subsidiary native—making an aggregate force of 295,840 men! The annual expense of the Anglo-Indian army is little short of £10,000,000. In 1830, according to Reports laid before Parliament, it was £9,374,000; and, since then, a very considerable increase has taken place, partly on account of the increasing extent of territory, and partly on account of the wars in Sindh, Afghanistan, and the Punjab. Some idea of the nature and composition of this immense force may be formed from the following items of expenditure in the year above-named:—Engineer corps, £83,874; artillery, £606,463; cavalry, £1,070,834; infantry, £4,124,079; staff, £481,490; medical staff, £132,490; pioneers, £74,511; commissariat, £614,327; sundries, £2,178,887. The army, native and European, is distributed throughout the country, at appointed stations, forming a chain of military posts, and keeping up a continual communication with the seats of the various presidencies.

The relations which subsist betwixt the Company and the tributary and dependent states may thus be described:—The Company undertake the defence of the dependent prince's territories against all enemies, domestic or foreign. He is bound, on the other hand, to enter into no alliances with other sovereigns or states without the Company's consent; and he pays them a certain annual subsidy out of his revenues for their protection, while he generally keeps up an army at the same time for the maintenance of internal tranquillity. In some cases, instead of paying a subsidy, the prince cedes a portion of his territories, of which the Company draw the entire taxes. The Company keep a resident at the prince's court, who is entitled to demand an audience at any time; and by this agent the Company do in fact interfere pretty regularly in the internal concerns of the state, particularly in settling the succession to the throne. The princes are in reality mere viceroys, or rather tax-collectors for the Company; and when in any state gross mismanagement or breach of engagement repeatedly occurs, these pageants are dethroned and pensioned off, and the Company take the government of the country into their own hands. The Company's protection is often found to shelter internal misgovernment; for the prince, being secured by the British army against the resentment of his own subjects, is tempted to indulge the more freely in extortion and oppression.

## REVENUE SYSTEM OF INDIA.

To sustain not only the above military force, but the civil management of India, a revenue of £18,000,000 requires to be levied. About two-thirds of this large sum is derived from a tax on land; and as the mode of collecting, imposing, and administering it, enters deeply into the system of Indian policy, and has a powerful influence on the social condition of the people, we shall here attempt its explanation.

Under the old Mogul empire, the sovereign was considered the universal proprietor of the soil; but the ryots, or cultivators, or actual owners, were held to have a perpetual right of occupancy, so long as they paid the fixed annual tribute or rent demanded by the sovereign. The rent was fixed at a third, and sometimes at a half, of the value of the produce, and the functionaries appointed to ascertain the amount leviable, and to collect it, were called *zemindars*. In 1793, Lord Cornwallis, governor-general, with a view to establish a better system for all parties, changed the *zemindars* from the character of hereditary tax-collectors to that of proprietors of the soil, though still accountable to government for the rent. This created a vast deal of misery at the time; thousands of poor ryots were ejected from their ancient possessions; but ultimately the country at large was benefited. It was arranged that the sum payable by the ryot for several years should be fixed as the permanent rent; one-tenth of this was allowed as the *zemindar's* share, and the other nine-tenths the proportion payable to the government or Company. The rent paid to the Company being fixed, great quantities of land which had been 'concealed'—that is, left out of the rough and partial returns formerly made, and which had lain in a wild state, or in pasture—were now put under crop. The practice is, to allow the ryot to occupy waste lands rent-free for three years, and to charge only a moderate rent for a few years more. In this way a considerable extension of cultivation has taken place; and some of the *zemindars* have acquired wealth. From their improvident habits, however, such wealth seldom lasts more than one generation; and no progress has been made towards the institution of a rural aristocracy. The Company have begun very recently to retrace their steps. When *zemindaries* fall into their hands, as they are always doing from time to time, by the inability of the holders to fulfil their engagements, the Company replace the ryots as nearly as they are able in their original situation, allowing them to hold their lands under payment of a rent which remains fixed, either permanently or

for a period of years. The Company in this case come in the room of the zemindar, and collect the rents in detail from the ryots by their agents.

This system of 'secondary settlement' prevails generally in Bengal, Bahar, Orissa, and Benares. It has also been tried on a small scale in the Madras presidency, but with indifferent success; but in a modified form it has long existed in some parts of Southern India, where hereditary chiefs, called *polygars*, occupy a similar situation to that of the zemindars in Bengal.

There are other two modes of collecting the rent or land-tax (for it may receive either name); the *Ryotwar*, and the *Mouzasawar* :—

The ryotwar was first extensively introduced by the late excellent Sir Thomas Munro, when governor of Madras in 1802. In this system the government collects the rent directly from the ryots, without the intervention of zemindars. An actual survey was made, with great labour and expense, of the lands of the villages, in which it was attempted to fix the extent and value not merely of every occupancy, but of every field. The records showed the whole sum which the village had paid in former years; and from this, with the opinions of practised assessors, checked and guided by the advice of the village *potail* and *curnum* (the headman and accountant), an estimate was formed of the gross produce, 45 per cent. of which was assumed as the rent. The sum thus ascertained was fixed as the maximum which the tenant should be called on to pay. The rent is taken from the ryots in monthly payments, and very summary means are used to extort it. The system was extremely unpopular at its introduction, and occasioned great distress; but this was attributed to the excessive amount of the tax, rather than to defects in its imposition. The reader should be told that the perquisites of the potail, curnum, Brahmin, astrologer, schoolmaster, and a long train of other village functionaries, are supposed to absorb 10 per cent. of the ryot's crop, so that the 45 per cent. which government took in a good year was, and was meant to be, one-half of the clear produce after this deduction was made. In consequence of the outcry against the tax, considerable abatements were made; and the ryotwar system remains in operation in a considerable portion of Madras presidency at this time, with, we believe, comparatively few complaints.

The third system is the *Mouzasawar*, or 'village settlement.' A village in India does not mean a collection of houses at a particular spot, but corresponds to what is called a township in America. 'It is a tract of country,' says Mr Hamilton, 'comprising some thousands of acres of arable and waste land; politically viewed, it resembles a corporation or township. Its proper establishment of officers and servants consists of the following descriptions:—The potail, or head inhabitant, who has the general superintendence of the affairs of the village, settles the disputes of the inhabitants, attends to the police, and performs the important duty of collecting the revenues within his village—a duty which his personal influence, and minute acquaintance with the situation and concerns of the people, render him best qualified to discharge: the curnum, who keeps the accounts of cultivation, and registers everything connected with it: the *taliar* (constable), or *totie* (watchman); the duty of the former appearing to consist in gaining information of crimes and offences, and in escorting and protecting persons travelling from one village to another; the province of the latter appearing to be more immediately confined to the village, consisting, among other duties, in guarding the crops, and assisting in measuring them: the boundary man, who preserves the limits of the village, or gives evidence concerning them in cases of dispute: the superintendent of the tanks and water-courses, who distributes the water therefrom for the purposes of agriculture: the Brahmin, who performs the village worship: the schoolmaster, who is seen teaching the children in the villages to read and write in the sand: the calendar Brahmin, or astrologer, who

proclaims the lucky or unpropitious periods for sowing and thrashing: the smith and carpenter, who manufacture the implements of agriculture, and build the dwelling of the ryot: the potman, or potter: the fisherman; the barber; the cowkeeper, who looks after the cattle; the doctor; the dancing-girl, who attends at rejoicings; the musician, and the poet. These officers and servants generally constitute the establishment of a village; but in some parts of the country it is of less extent, some of the duties and functions above described being united in the same person; in others, it exceeds the number of individuals which have been described. Under this simple form of municipal government, the inhabitants of the country have lived from time immemorial. The boundaries of the villages have been but seldom altered; and though the villages themselves have been sometimes injured, and even desolated, by war, famine, or disease, the same name, the same limits, and even the same families, have continued for ages. The inhabitants give themselves no trouble about the breaking up and division of kingdoms; while the village remains entire, they care not to what power it is transferred, or to what sovereign it devolves; its internal economy remains unchanged; the potail is still the head inhabitant, and still acts as the petty judge and magistrate, and collector or renter of the village.'

It will be understood that under the secondary settlement the government transacts with one individual for an extensive district, probably as large as a county; under the mouzasawar or village settlement, it transacts with the chief person of the village for the whole community; and under the ryotwar settlement, it transacts with each individual cultivator. It may be proper to add, that in India a ryot seldom holds more land than he and his family are able to cultivate, and that there are few farm-servants in our sense of the word.

Of the three modes of settlement, it may be stated that the secondary plan has yielded the largest revenue; the method of 'village settlement' does not cause much more trouble to the government, and is better liked by the cultivators; the ryotwar is the most expensive and troublesome, and has been the least productive of revenue; but it would be the most equitable and most advantageous to the people at large, if the ends of justice were not defeated by the frauds of the native functionaries intrusted with its details, and whose corruption is almost universal.

The revenue derivable from land by these various processes of exaction amounts, as has been said, to two-thirds of the whole revenue of the Company, or the sum of £12,000,000. The next greatest head of revenue is the receipt from native princes, or from ceded and conquered countries, and which averages in amount from £6,000,000 to £7,000,000.

The Company have hitherto gained £1,000,000 sterling per annum by the monopoly of opium. They have offered a price annually, which has been fixed at the lowest rate that will remunerate the producer; and ryots, whose lands have been suited to the cultivation, entered into engagements to deliver certain quantities. About two-thirds of the opium used to be smuggled into China, until the Chinese stopped the importation; and one-third was sent to the eastern isles, Java, Sumatra, &c. Salt has also been an article of valuable taxation. It has been manufactured on the coast of the Bay of Bengal exclusively for the Company. Before it reaches the consumer, its price is enhanced five, eight, or ten fold. The Company have realised a gross revenue of £2,000,000 per annum from this monopoly.

The customs drawn by the Company consist partly of taxes collected at the seaports on foreign goods brought in, and partly of *transit* duties, levied on goods passing through the country. There are provincial duties, paid in passing from one presidency to another; town duties, on certain articles at the gates of towns; and market duties, levied at the market stations where fairs are held. To collect these taxes, and guard against contraband trade, there are customhouses, called *chekies*, at every considerable village. In the single district

of Madura, with a million of souls, in the Madras presidency, there are twenty-one customhouses, each of which has four or five subordinate establishments; and at these stations, even when no duties are exigible, fees are charged by the native officers for the trouble of examination, and a good deal of delay is caused in the transmission of merchandise. These taxes are sources of annoyance and occasional extortion to the trading classes. They produce a gross sum of £1,800,000, which is reduced to £1,600,000 by the charges of collection, &c. We believe that a considerable portion of the revenue derived from these duties on traffic is laid out by the Company in the construction of roads and bridges, where improvements of this kind are most wanted.

In 1843-4, the annual revenue was £17,015,973, but this large sum did not cover the expenditure, including interest on the debt due by the Company, which now amounts to about £40,000,000—the actual deficiency being £772,322. As India, by the taxes which it contributes to the Company, clears the cost of its own protection and all its other expenses, it may be considered as the only foreign possession of Britain whose connection is not a cause of loss to the mother country. By means of its vast import trade, India forms one of the best customers for British manufactures, and is therefore a source of wealth to the United Kingdom. [For particulars of export and import, see RESOURCES OF BRITISH EMPIRE, No. 62.]

As may be generally known, an act of parliament was passed in the year 1813, permitting the free trading of British subjects with India, reserving the commerce of China to the Company; the territorial and commercial branches were separated, as well as all accounts connected with them; and the sovereign was empowered to create a bishop of India, and three archdeacons, to be paid by the Company. This act, which was in force till the 22d day of April 1834, did not afford perfect freedom of trade to India, yet it led towards that desirable result, and greatly increased the commerce with the East. By the act 3d and 4th Will. IV. cap. 85, passed in August 1833, entitled 'An act for effecting an arrangement with the East India Company, and for the better government of his Majesty's Indian territories, till the 30th day of April 1854,' the Company were deprived of the exclusive right of trading with China, and ordained to close the whole of their commercial business, and make sale of their merchandise, stores, and effects, so far as regarded commercial assets. It was further ordained that the whole debts of the Company should be chargeable upon the revenues of their Indian territories, but leaving a yearly dividend of 10 per cent. to be retained by the Company; this dividend to be redeemable by parliament. The Company to pay into the Bank of England £2,000,000 annually, till the sum of £12,000,000 is accumulated, as a security fund to the government. The other principal provisions were—A board of commissioners, to be appointed by the king, to superintend affairs of India; Bengal presidency to be divided into two presidencies—Fort-William (Calcutta) and Agra; the whole government, civil and military, of India, to be vested in a governor-general and councillors.

The 81st clause is in these terms:—'And be it enacted, That it shall be lawful for any natural-born subject of his majesty to proceed by sea to any port or place having a customhouse establishment within the said territories, and to reside thereat, or to proceed to and reside in, or pass through, any part of such of the said territories as were under the government of the said Company on the 1st day of January 1800, and in any part of the countries ceded by the nabob of the Carnatic, of the province of Cattack, and of the settlements of Singapore and Malacca, without any license whatever; provided that all subjects of his majesty, not natives of the said territories, shall, on their arrival in any port of the said territories, from any port or place not within the said territories, make known in writing their names, places of destination, and objects of pursuit in India, to the chief officer of the customs,

or other officer authorised for that purpose, at such port or place as aforesaid.' Clause 86 permits his majesty's natural-born subjects to purchase lands in India: 87 enacts that no native of India, or natural-born subject of his majesty, shall, by reason only of his religion, place of birth, descent, colour, be disabled from holding any place, office, or employment under the Company: 112 enacts that the island of St Helena be placed under his majesty's government.

By this act it will be perceived that several very important provisions are made for the benefit both of Hindoostan and Great Britain. India is henceforth open to the settlement of British emigrants; trade may be carried on freely with either India or China; and Indo-Britons, Hindoos, or other natives, are now placed on a level as to political, military, or civil distinctions, with Englishmen. It is stipulated that the governor-general in council is empowered to legislate for India, and for all persons, whether British or native, foreigners or others: if the laws thus made by the governor-general are disallowed by the authorities in England, they shall be annulled by the governor-general. In virtue of these arrangements, it is evident that India, with all its social improvements, retains very much of the character of a despotically-governed country; no part of the population having any right to interfere in the legislation or executive. To enlightened foreigners this may prove an inconvenience; but in the extraordinary condition of the whole Indian territory, a more liberal policy would most likely be unsuitable, if not injurious. As it is, England may expect to derive very great advantages from the policy pursued. To use the words of Dr Wallich, superintendent of the Company's botanic gardens at Calcutta—'The Company's territories in India are productive of every article which can conduce to the happiness of men; and it only requires skill, and ingenuity, and encouragement, both to the natives and Europeans in India, to select everything that can possibly be desired.' As the Indian population possess a taste for British manufactures, a reciprocal benefit will be the result of every increase of intercourse.

#### NATIVE POPULATION—HINDOOS.

The bulk of the population of India is composed of Hindoos, the primitive inhabitants of the country, and forming one of the most ancient nations in the world. This race was distinguished for their humanity, gentleness, industry, and were polished by letters and arts, at a time when most of their Asiatic neighbours were yet only in the first stages of civilisation. This remarkable people have preserved their national character for thousands of years, even under the dominion of foreigners, and have retained to the present day their language, their written characters, their local government, religion, manners, customs, and habits of life. The Hindoos are in general of a brownish-yellow complexion, but the higher and richer classes are almost as white as Europeans. They are somewhat above the middle height, well proportioned, and very flexible and dexterous. Temperance, frugality, hospitality, and obliging manners, are the favourable traits in their character; but they are now reproached with indolence and avarice. With proper discipline, they form excellent soldiers and faithful servants of the Company. They possess great natural talents, but are at present deprived of opportunities for their development. They practise agriculture, breeding of cattle, fishing, hunting, and mining, and are largely engaged in manufactures, commerce, and navigation. They manufacture cloths of great variety and value, particularly cotton and silk, among which are the finest muslins and shawls, mats, cordovan leather, &c. and are imitable in dyeing. In the arts of music and singing they are backward, but in dancing, statuary, and architecture, they are more advanced. They are acquainted with arithmetic, astronomy, and chronology, and are fond of poetry.

The most extraordinary peculiarity in the Hindoos is their division into *castes*, or perfectly distinct orders of society, which have existed from the remotest times.

There are four castes, and it is strictly enjoined by the Hindoo religion that no transition from one to another shall take place: no connection between them by marriage or any other way is allowed, and no individual of one class can assume the habits or engage in the occupations of another. The distinction is complete in every sense, hereditary and personal; all the privileges or disabilities are inherited; no one is permitted to become what he is destined to be by his natural abilities, but is obliged to become only what his birth permits, or to remain what it condemns him to be. The slightest transgression of these laws is punished with loss of caste, and sometimes, in particular cases, with death. Even the difference of food is precisely marked out. The three higher castes are prohibited entirely the use of flesh; the fourth is allowed all kinds except beef; all others are outcasts, and may eat what they please. Thus the lower the rank of the Hindoo, the less he is restricted in the matter of meat and drink; but, on the other hand, the burdensome restrictions increase with the inferiority of rank.

The first, or most noble caste of the Hindoos, are denominated Brahmins; they are priests, scholars, teachers, lawyers, and state officers, and are required to be virtuous, learned, peaceable, just, and self-denying. The second order is the Kyetra, who are kings and warriors; and they are required to have a thirst for glory, to die rather than retreat, and to be generous to captives. They preserve the ancient name of Rajah-poots, by way of distinction, in their old hereditary dominions. The third order, which is called Bhysya, or Vaia, are husbandmen and merchants. The fourth caste is that of the Soodras, who are labourers, and they are enjoined to serve with patience and fidelity. A lower caste, if it can be called such, are the Paria—those unhappy beings who have lost their station in the noble orders, and who are obliged to do whatever no one else can do without pollution. They are not only reckoned unclean themselves, but they render unclean everything they touch. They are deprived of all civil privileges, and stigmatised by particular laws, regulating their mode of life, their houses, and their furniture; they are not allowed to enter the temples of the other orders, but must worship by themselves. Their houses are miserable hovels, distant from cities and villages.

The Brahmins, who are not legitimately entitled to possess property, and who must live upon the bounty of others for their support, cherish in the people the most debasing superstitions, and exact from them the most profound veneration. Instead of being holy, harmless, and undefiled, they are vicious, tyrannical, avaricious, and to the last degree impure. This infamous aristocracy is the curse of India, and presents a barrier to the attempts which have been made to meliorate the condition of the inferior orders. We believe the Kyetra and Bhysya castes are nearly extinct, and that the Hindoo nation is now composed principally of Brahmins and Soodras, with their subdivisions. These subdivisions are innumerable:—Every trade, every peculiar department of service, has its class, therefore the retinue of servants to be kept is very large; for the man who carries in your water cannot wait at table, nor the man who cooks a dinner serve it up, nor the servant who waits at table sweep the room; and the same kind of classification goes on through all the pursuits of life. In a number of instances, Brahmins have become soldiers in the service of the East India Company, but without engaging in menial employments; and they still claim precedence even of kings in point of etiquette. This rigorous classification of the Hindoos undoubtedly presents an obstacle to the advancement of Christianity, which, though hardly thought of by the British at home, is next to insurmountable, and will retard proselytism for an almost indefinite period.

From recent investigations, it appears that the foregoing rigorous classification of the Hindoos is much less an obstacle to improvement in manners than was formerly supposed. It would seem that the classification

is more theoretic than practical. The altered state of society has obliged members of the aristocratic caste to engage in divers employments or trades not permitted by their religion; and to accomplish this object, various subterfuges and self-deceptions are practised. Besides, there have arisen a prodigious variety of subdivisions by the intermixture of castes; and the employments allowed to these mixed or impure castes may be said to be every description of handicraft and occupation for which the wants of human society have created a demand. In point of fact, we are told by the best authority, that men of all castes may be seen working together in one handicraft employment. A kind of purity of caste is perhaps, nevertheless, kept up by the members of different castes not eating with each other, or not eating forbidden things. It is related that purity of caste is sustained by means of clubs or lodges scattered throughout Hindoostan, and existing in considerable force in every large town; yet it seems that excommunication from these fraternities is, upon the whole, unable to prevent the breaking down of ancient habits, or to subdue the disposition to imitate the English in the arts of civilised life. The Hindoo races are indeed described as now exceedingly anxious for improvement; and it is rational to expect that through the means of schools for education, and a conciliatory behaviour on the part of their British neighbours, they will attain no small degree of cultivation.

#### HINDOO RELIGION AND LANGUAGE.

The religious belief of the Hindoos is called Brahminism, and is founded on a most extensive collection of sacred records, of which the Brahmins are allowed to be the sole expounders. 'These sacred writings,' says Mr Statham, in his 'Indian Recollections,' are of two kinds—the Vedas and Shastres. The former may be termed their Scriptures, the latter expositions of them. Beass Muni—that is, Beass the Inspired, a prophet who lived in the reign of Judistheer, on the banks of the Jumna, near the present city of Delhi, collected all the detached pieces which form the Vedas, from all parts of India, and gave them their present form and arrangement. They are divided into four books, all written in the Sanscrit. The first book is called Rug Veda, which signifies the Science of Divination, concerning which it principally treats. The second is distinguished by the title of Sheham, which signifies Piety or Devotion, and this book treats of religious and moral duties. The third is the Judger Veda, which, as the word implies, includes the whole science of Religious Rites and Ceremonies. The fourth is denominated Obater Bah: in the Sanscrit, *obater* signifies the being or essence, and *bah*, good; this, literally interpreted, is the knowledge of the Good Being, and accordingly this book comprehends the whole science of theology and metaphysical philosophy.

The Vedas, as also the Shastres or commentaries, pretend to great antiquity; so much so, that many Europeans have been strangely staggered in their belief of the Mosaic chronology by reading them. But it only requires a little consideration and research to discover a vein of imposition running through the whole of their details. They reckon the duration of the world by four ages, extending altogether to about eight millions of years; but the fallacy of this reckoning has been fully exposed by astronomical observation. The idea which the Shastres give of God is, that there is one Supreme Being, whom they style Bhogabon or Esher, sometimes Khodah; proceeding from him are three powers or deities—namely, Bruhmha, the Creator of all; Vishnu, the Preserver of all; and Seeb or Shera, the Destroyer of all. Now, whilst the latter is worshipped by all, the former has scarcely any attention paid to his temples; and even Vishnu, the Preserver, has few votaries compared with the destroyer Seeb. Subordinate to these are 330,000,000 inferior gods and goddesses, each representing some peculiar virtue or vice. The Hindoos suppose that each of the three presiding powers oftentimes seeks to encroach upon the

prerogative of his compeer, and thus are often quarrelling and seeking to subvert each other's arrangements.'

One of their most superstitious practices consists in worshipping or deifying the waters of the Ganges. This large and beautiful river extends from west to east across an extensive district in Hindoostan Proper, and with its tributaries may be reached by a very large proportion of inhabitants in the most populous and productive part of India. The sacred ceremony of adoring the Ganges consists in the population crowding morning and evening to bathe in it, and quantities of the water are carried to all parts of India, and are sworn by in courts of justice.

The cow is an animal held sacred among the Hindoos, and cow-dung is used in the temples and other places as a species of holy ointment. The lotus, a plant with tall luxuriant leaves, is likewise held in deep veneration. Some of the temples or pagodas of the Hindoos are of high antiquity and gigantic conception, majestic appearance, and tasteful architecture. The entrance is always made in a huge pyramid, in a number of storeys, which gradually grow narrower as they approach the top. Inside may be seen the cow lying down, a serpent, or some other object of adoration. Here sacrifices take place. One of the most extensive pagodas of India is that of Juggernaut, whose towers are seen at twenty miles' distance. Here, as at other places, there are processions of idol cars, large heavy ornamented structures, which are dragged along by the multitude amid the shouts of assembled thousands. As the wheels pass swiftly on, self-devoted victims rush forward, throw themselves before them, and are crushed to death, exulting in the hope of thus securing a passage to the celestial abodes. The practice of widows sacrificing themselves on the funeral pile of their husbands, is another horrid rite; but it has been suppressed in recent times by the British government.

Besides Brahminism, there are a variety of religious beliefs and sects in India, but all less or more founded on the most gross superstitions. Each possesses its own temples, images, and orders of priesthood. The Boodhists, previous to their violent expulsion by the Hindoos, were second in point of numbers; but their religion is now little known in India, and is confined chiefly to Thibet, Birmah, Siam, and Ceylon.

There are, it is believed, four original languages in India, and of these there are some hundreds of dialects, differing less or more from each other and from the originals, and maintaining also a partial distinction from the introduction of Arabic, Persian, and other foreign words. While, however, each tribe has its own peculiar dialect, all use one language, the Sanscrit, in their sacred writings. The Sanscrit is a dead language, though probably once spoken; it is wonderfully perfect in its construction, and extremely copious. Its alphabet is called *Devanagari*, divine alphabet, because it is said to have had its origin from the gods, whose language it is; it consists of fifty letters, and has three genders. The next language in estimation is the Pracrit, which comprehends the various dialects used in common writing and social intercourse. The dialects of the Pracrit are spoken in Bengal, and include that which is called Hindoostanee, the principal spoken tongue in India.

#### MOHAMMEDANS AND OTHER CLASSES.

According to Mr Hamilton, 'the modern Mohammedans may with safety be estimated at one-seventh of the total population; and notwithstanding the subversion of their political predominance by a Christian power, their religion continues to expand. They are no longer, however, the sanguinary zealots who, eight hundred years ago, in the name of God and the prophet, spread desolation and slaughter among the unconverted pagans. Open violence produced little effect on so patient a people; and although the Mohammedans subsequently lived for centuries intermixed with Hindoos, no radical change was produced in the manners or tenets of the latter; on the contrary, for almost a century past, the Mohammedans have evinced much defer-

ence to the prejudices of their Hindoo neighbours, and a strong predilection towards many of their ceremonies.' The warlike portion of the Mohammedans having recently been dislodged by the British from the Mahratta courts, where they had found shelter, they have been obliged to seek employment in inferior stations. The Mohammedans of India are more intelligent, and possess greater strength and courage, than the Hindoos; but they are also more proud, jealous, revengeful, and rapacious, and their fidelity is much less relied on by the British government. In some districts the Mohammedan population is nearly as numerous as that of the Hindoos, and both seem to live in a state of mutual amity.

Besides the Hindoos and Mohammedans, there are various scattered tribes in India, of a very different character from either, and often inhabiting mountainous tracts of country, and called Garrows, Mongula, Tartars, &c. Among the different races is found that of the Parsees or Persians, the ancient worshippers of fire, long since driven from their native country by the persecuting sword of the Arabs. Many of this people are opulent, and they take the lead in the commercial transactions of Bombay, Surat, and other north-western parts. Their general conduct is quiet and respectable.

Notwithstanding what has been related of the strictness of the Hindoos regarding modes of living, they seem liable to fall in with European usages. In Calcutta and other large towns, many of the wealthy natives imitate the British in their dress, household furniture, equipages, and style of living, and show a strong desire to mix in their social parties, to which, however, they rarely find access. The English take no pains to conciliate the friendship of the native tribes, however well behaved and intelligent they may be. 'Of this foolish, surly, national pride,' says Bishop Heber, 'I see but too many instances daily, and I am convinced it does us much harm in this country. We are not guilty of injustice, or wilful oppression, but we shut out the natives from our society, and a bullying, insolent manner is continually assumed in speaking to them.' The exclusiveness of this species of hauteur is perhaps fully more remarkable with respect to that class of persons who have drawn their origin from the intercourse betwixt the English and natives. These Indo-British, as they are called, form a part of the population of Calcutta, and are a very interesting and increasing people. 'Many of them,' says Statham, 'are very opulent, and others can vie with the more cultivated of their European neighbours in literary attainments; notwithstanding this, there is a marked contempt shown them by Europeans generally. If a European lady should wed with an Indo-Briton, the doors of all the higher circles would be closed against her, however rich the man of her choice might be.' This state of things will happily be modified by the provisions of the act already noticed.

#### RURAL CHARACTERISTICS AND PRODUCTS.

In the large and fertile territory of Bengal, as well as in all other parts of India where the cultivation of the soil is pursued, the art of the husbandman is, as may be expected, still in the rudest state; and in every quarter there exists great room for improvement, which nothing could so well facilitate as the settlement of intelligent European families. In the inundated districts of Bengal, rice is the main crop which is raised, at least during the wet season: it grows to its greatest height while the lands are overflowed, and is frequently reaped by men in canoes, the ear only being cut off, and the stalk left. When the peasants go to market during the height of the flood, they take their families with them, lest the house should be washed off during their absence with the boats. Rice is the summer crop, requiring much heat and moisture; but during the cool dry season, from November to April, they sow and reap another harvest, consisting of wheat, barley, or different kinds of pulse: this is called the *dry crop*, because it is reaped without flooding the lands;

the rice being considered as the *wet crop*, for a contrary reason. There are therefore two seed-times and two harvests. Besides these regular crops, many small grains are sown, which are limited to no particular season of the year, and which reward the industry of the cultivator with a rich vegetation at all times.

Besides the different kinds of grain, the farmers of Bengal raise a number of other products, of great value. Of these, one of the principal is indigo: this is a small plant, shrubby in its growth, but in its leaves and flowers very much like the common tares of this country; it is sown during the rains, and raised in rows or drills. The leaves only are useful, on which account it is cut repeatedly, without being allowed to flower, which would make it drier and less juicy. The leaves are steeped and beaten in a vat among water; after which the liquid is strained through cloths, and set to evaporate in shallow troughs placed in the shade. This is soon effected in that warm dry climate; and the indigo is then found deposited in a crust at the bottom. The process requires much preparation and expense; and it has only succeeded well since the country has enjoyed peace, and there has been a prospect of employing large capitals with security. It now produces, however, a large return to the cultivators; and gives a new source of wealth to the country. It is cultivated along the whole course of the Ganges up to Delhi, and is an annual in the lower, but a triennial in the upper provinces. It succeeds best on overflowed grounds, and in dry seasons is apt to fail. The number of factories of indigo in the Bengal presidency is estimated at 800 or 400. A few of them belong to natives; but they are chiefly in the hands of Englishmen, who take leases of 10,000 or 20,000 acres of land, in the name of native servants (not being allowed to hold it in their own), from a zemindar for the purpose. They encourage the ryots (native cultivators) to raise crops of the plant, by making advances to them in money. They purchase the produce at a price agreed on, and erect works for extracting the dye from the plant; the whole of the operations being generally conducted by native labourers, under native superintendents. It is observed that the establishment of such factories raises the value of land, extends cultivation, and spreads a certain degree of improvement in the villages. The importation of Bengal indigo into Britain began about forty years ago, and has since increased to an amazing extent. It is calculated that about 11,000,000 lbs. are annually exported from the country, of which 7,000,000 lbs. come to Britain, and the rest goes to America, France, Germany, Sweden, &c. In Bengal alone £1,680,000 are expended for rent and labour in its production, and it realises in Europe a sum of £3,600,000. In the countries named, Bengal indigo is silently obtaining a preference over every other.

Silk is raised in great quantities in Bengal and Orissa, between the latitudes of 22° and 26°, and it has hitherto been very nearly a monopoly in the hands of the Company. It is chiefly produced by the native Indian worm, which affords four crops, or sometimes six in the year: the Italian worm, which was introduced half a century ago, yields only one crop a year, but of a finer quality. The Indian silk, compared with the best European varieties, is 'foul, uneven, and wants staple;' but its cheapness has brought it into extensive consumption. The Company have eleven factories, or 'filatures,' which form the centres of 'circles,' within which the cultivation of silk is carried on, each having a certain number of subordinate stations. The silk, in the raw state, is purchased from the ryots at the factories or sub-factories, wound off the cocoons, and prepared for transmission to Europe. About 2,000,000 lbs. are annually brought to England, of which a very small quantity (one per cent.) is equal to the finest silk; the mass of it is decidedly inferior. There is strong ground to conclude, however, that the production of silk in India will yet be greatly increased.

Cotton has long been cultivated by the natives in all the three presidencies. It is universally of the kind

called 'short staple,' and being coarse in quality, and badly cleaned, it fetches only two-thirds of the price of American short staple in the British market. The best quality comes from Bombay (the Guserat); the next from Madras; and the worst from Bengal. The cultivation being entirely in the hands of the natives, is rudely conducted; and in particular, pains are not taken to renew the plant constantly from the seed, as the Americans do with the most advantageous results. Experiments have been made under the sanction of the Company, and by private individuals, to introduce and cultivate finer species than those in use, but they have generally been failures. There is no doubt, however, that by the introduction of European capital and skill, the quality of Indian cotton may be much improved, and what is raised sent to the market in a much cleaner and better condition. The exports of cotton from India to all countries amounted lately to 72,000,000 lbs., of which only a third part came to Great Britain.

The cultivation of the sugar-cane is pursued with great success in Bengal and other parts of India, but chiefly by the natives, for domestic use. The process of bruising the canes is on a rude plan, and the sugar which is produced is from this or some other cause very inferior to the sugar of the West Indies. In no article of produce is there greater room for improvement than in this. The cultivation of the cane requires great care and skill, and the mechanism for extracting and preparing the sugar can only be erected at a great outlay of capital. It is anticipated that when Europeans are permitted to hold lands freely, and to embark capital on sugar plantations, sugar of good quality may be manufactured much cheaper than in the West Indies, where the price of labour is much higher.

The bamboo, a species of cane or reed, is much cultivated in Bengal. It grows to the amazing height of forty feet; and though it arrives at perfection in two years, it has all the firmness of the hardest timber. It has joints like a reed, or like grass, and is, like them, quite hollow; yet it is so strong that the porters of the country use it for suspending the heaviest burthens between their shoulders. It is used for beams and uprights in building houses; and being protected from damp by a kind of natural varnish, it will last in such situations for a hundred years. It serves also for making bridges, for the masts of small boats, and for innumerable other purposes; yet of this useful material, one acre of land will yield ten times as much as the same space will produce of other wood. None of the productions of India puts so many conveniences, in regard to furniture, houses, boats, &c. within reach of the poorer classes, as the bamboo. It would require a volume to mention even the names of the plants useful to man which flourish in the luxuriant soil of Bengal. Cotton, tobacco, the opium poppy, rape (which is cultivated for the sake of its oil), cucumbers, vegetable marrow (as one of the gourd tribe is called), and innumerable other plants, always afford a plentiful harvest. Of fruit-trees there are the mango, which is something like our peach, the date-tree, the tamarind, the guava, the pomegranate, and others. Another production, which is peculiar to warm climates, and which grows in high perfection along the sea-coasts, is the cocoa-palm. This tree would of itself be almost sufficient for the subsistence of mankind in the countries where it grows, so various and useful are its products; indeed there are some populous islands—the Maldives and Laccadives—where little else is cultivated.

In the interior of India, the tea-plant is said to flourish, and is likely to become of great importance to the trade of the country. Districts lying between the 26th and 28th degrees of north latitude, and the 94th and 96th degrees of east longitude, are described as possessing this shrub in abundance, and of a quality equal to that of China. In Assam, which lies between Bengal and Thibet, the attempt has lately been made to cultivate and gather the product of the tea-plant for purposes of commerce. In 1838, ninety chests of it were imported into London, and found to be of a good quality.

## EAST INDIES.

Persons skilled in the gathering and preparation of the leaves have been introduced from China; and there seems little reason to doubt that Assam is capable of producing tea to any extent, if sufficient capital and enterprise were exerted in the undertaking.

### CHIEF CITIES.

*Calcutta*, the British capital of India, is situated about 100 miles from the sea, on the east bank of the Hoogly, a branch of the Ganges, in latitude 22° 23' north, longitude 88° 28' east. The length of the town is about 6 miles along the bank of the river. When seen from the south, on which side it is built round two sides of a great open plain, with the Ganges on the west, it presents the view of a very noble city, with tall and stately houses ornamented with Grecian pillars and spacious verandas. The esplanade between the town and Fort-William leaves a grand opening, along the border of which is placed the new and splendid government-house, erected by the Marquis Wellesley. Fort-William, which was commenced by Lord Clive, is the largest and strongest fortress in India, but is considered too extensive to be easily defended: its garrison usually consists of two European regiments, with artillery, besides a supply of native troops. The public buildings of Calcutta, besides the government house, are a town-hall, a court of justice, two churches of the established religion, and one for the Scotch Presbyterian worship, which is a very handsome edifice. There are also several chapels for other religious bodies, mosques, and pagodas—the latter generally decayed and ruinous, the religion of the people being chiefly conspicuous in their worship of the Ganges. Behind the elegant front lines of houses is ranged the native town, deep, black, and dingy, with various crooked streets, huts of earth baked in the sun, or of twisted bamboos, interspersed here and there with ruinous brick bazaars, pools of dirty water, cocoa-trees, and little gardens, with some fine large dirty houses, the residences of wealthy natives. 'Fill up this outline,' says Bishop Heber, in his valuable Correspondence, 'with a crowd of people in the street, beyond anything to be seen even in London, some dressed in tawdry silks and brocades, more in white cotton garments, and most of all black and naked, except a scanty covering round the waist, besides figures of religious mendicants with no clothing but their long hair and beards in elf-locks, their faces painted white or yellow, their beads in one ghastly lean hand, and the other stretched out like a bird's claw to receive donations; marriage processions, with the bride in a covered chair, and the bridegroom on horseback, so swathed round with garlands as hardly to be seen; tradesmen sitting on the ground in the midst of their different commodities, and old men, lookers on, perched naked as monkeys on the flat roofs of the houses; carts drawn by oxen, and driven by wild-looking men with thick sticks, so unmercifully used as to un deceive perfectly all our notions of Brahminical humanity; attendants with silver maces pressing through the crowd before the carriage of some great man or other; no women seen except of the lowest class, and even these with heavy silver ornaments on their dusky arms and ankles; while coaches, covered up close with red cloth, are seen conveying the inmates of the neighbouring seraglios to take what is called "the air;" a constant creaking of cart wheels, which are never greased in India; a constant clamour of voices, and an almost constant thumping and jingling of drums, cymbals, &c. in honour of their deities; and add to all this a villanous smell of garlic, rancid cocoa-nut oil, sour butter, and stagnant ditches, and you will understand the sounds, sights, and smells of what is called the "Black Town" of Calcutta. The singularity of this spectacle is best and least offensively enjoyed on a noble quay which Lord Hastings built along the shore of the river, where the vessels of all forms and sizes, Arab, Indian, Malay, American, English—the crowds of Brahmins and other Hindoos washing and saying their prayers—the lighted tapers, which, towards sunset, they throw in, and the broad

bright stream which sweeps by them, guiltless of their impiety and unconscious of their homage—afford a scene such as no European and few Asiatic cities can at all parallel in interest and singularity.'

In recent times considerable improvements have been made in and about Calcutta, jungles being cleared away, streets drained, and stagnant water removed. Though the situation of Calcutta has not been well chosen, it is excellently adapted for commerce. At high water the river is here a full mile in breadth. The advantages possessed for inland navigation are considerable; foreign imports may be transported with great facility, on the Ganges and its tributaries, to the north-western quarters of Hindoostan, while the valuable productions of the interior are received by the same channels. There is at all times a vast quantity of merchandise deposited at Calcutta, and the trade carried on is now very extensive. Besides a government bank, there were lately two private banks, which circulate to a considerable amount. There are several daily, twice-a-week, and weekly newspapers; and recently a quarterly review. The religious, and charitable, and educational institutions are numerous, and of great service. Society in Calcutta is gay and splendid; and the British inhabitants among their own class are described as hospitable, though jealous of etiquette, and of an overbearing disposition. There are no hotels, or inns, or lodging-houses of any description—a want which appears perfectly amazing—and all strangers, male or female, must be provided with introductions to the houses of residents. The expenses of living are very considerable; and as there are now no more opportunities of acquiring wealth by the spoliation of native principalities, fortunes are much seldomer realised than formerly. There being also now fewer deaths, there are fewer chances of promotion.

The population of Calcutta is composed of about 14,000 Christians, 48,000 Mohammedans, and 120,000 Hindoos; but this is the amount only within the city proper. If the environs or suburbs be included, the population will amount to perhaps 500,000; and so densely peopled is the surrounding district, that within the circuit of twenty miles there is a population of nearly two and a-half millions. In 1841 the exports of Calcutta amounted to £5,867,767, and the imports to £8,869,329.

*Madras*, the seat of government of Southern India, is situated in the Carnatic, on the shore of the Bay of Bengal, in latitude 13° 5' north, longitude 80° 21' east. The shore is here low, and dangerous to approach by vessels. On the beach stands Fort St George, a place of considerable strength, and which may be easily defended by a small garrison. A noble range of public edifices, including a customhouse and courthouse, also adorn what is called the north beach. Madras differs in appearance from Calcutta. It has properly no European town, the settlers residing in their houses in the midst of gardens, and transacting business in the district appropriated to the residence of the natives. The principal church in Madras, St George's, is a beautiful edifice. There are many excellent charities here; and the school for male and female orphans, into which the philanthropic Dr Bell introduced the Lancastrian system of education, is superior to anything of the kind in Calcutta. The society of Madras is more limited than that of Calcutta, but the style of living is similar. The roads in the vicinity are excellent, and afford most agreeable drives to the European residents. According to Heber, 'the native Christians are numerous and increasing, but are unfortunately a good deal divided about castes.' The Armenians are here numerous, and some of them wealthy. A Scotch Presbyterian church has been some time erected. The population of Madras and its suburbs has been stated at upwards of 400,000. In 1841 the exports of Madras amounted to £1,780,000, and the imports to £3,000,000.

*Bombay*, the seat of government for the western parts of India, is a small rocky island, lying on the west coast of Hindoostan, in latitude 18° 56' north longitude

72° 57' east. Bombay was originally some hilly rocky islets, but these, by the influence of the high tides, have been joined to each other; and now the island is composed principally of two unequal ranges of whinstone rocks, extending from 5 to 8 miles in length, and at the distance of about 3 miles from each other. All the ground that can be cultivated is now laid out in agriculture, and the remainder is either barren or covered with the residences of Europeans and natives. These residences are on wet, low, and unhealthy grounds, ever below high-water mark; and from this and other circumstances, Bombay is described as being the most insalubrious of the presidencies. The fort of Bombay is situated at the south-eastern extremity of the island, on a narrow neck of land. The chief advantage of Bombay is its deep tide-water, which permits the most extensive system of maritime trade: excellent docks are erected for the accommodation of the shipping. Bombay is the seat of very extensive trade with the Persian Gulf on the north, as well as with the south of India. Cotton is the principal article of export. The population is stated at about 180,000, composed of Christians, Jews, Mohammedans, Hindoos, and Parsees. In 1841 the exports of Bombay amounted to £5,160,769, and the imports to £5,577,315.

## MISCELLANEOUS PARTICULARS.

The preceding brief sketches can convey but a feeble idea of the immense extent and varied character of the Indian empire, as well as of its vast capabilities and importance as a possession of Britain. In India, the European traveller is everywhere charmed with the wild grandeur of the scenery and the luxuriance of the soil; and he is equally surprised at the density of the population, and the traces of superstitious observance, which meet his eye. The people for the most part live in an exceedingly simple manner. Much of their food requires no cooking; plantains, cocoa-nuts, pumpkins, and other fruits, being more palatable raw than dressed. The chief cooked article is rice. Houses are made of bamboo or cajann stakes, without splitting, planing, or dressing of any kind; they are then woven together with small twigs equally unprepared; the whole is plastered over with mud from the nearest clay-hole, and then thatched with cocoa-nut leaves fresh from the tree. Oars for their boats are only bamboos, with a round board tied to the end; the masts are two or three of the same bamboos lashed together with strings. Drinking cups are made of a large nutshell, with one end rubbed off on a stone; a most palatable and wholesome drink is found in the juices of the cocoa-nut palm, which is received into an earthen jar as it drops from the point of a broken branch; and its only preparation is straining through a kind of natural sieve, which is found at the roots of every leaf on the tree. The common people wear little or no clothing; and when it rains, their only umbrella is formed of a number of palm-tree leaves sewed together by the edges into a shape resembling a cradle cut across, which covers their head and back. All processes of manufacture and handicraft are on the rudest possible scale, and carried on without what we term capital. The people only scratch the ground instead of ploughing it; they never apply any manure; their corn is thrashed by setting bullocks to tread upon it; the smith's anvil is the nearest stone, his bellows a rough goat-skin; a shoemaker tans the raw hide one day, and makes shoes of it the next, sitting the whole time at the door of his customer; the weaver's apparatus needs but the shadow of a tree for shelter, and it can be removed at an hour's notice to any other tree which is more convenient. Even their distillery needs only an earthen kettle, some cold water, and a few bamboo reeds for a worm; and with these they produce liquors as intoxicating and pernicious as any manufactured by the science of Europe. This absence of skill in all the processes of industry, renders the labour of the working-man of very slight value: hence he never receives more than what is barely necessary for subsistence; and the mass of

the people are consequently at the lowest ebb in regard to domestic accommodations or mental acquisitions.

Simple as the bulk of the population is, there are not wanting scattered tribes and families dexterous both in cunning and crime. In the accounts of all travellers, it is mentioned that there is no possibility of travelling in almost any part of the interior in safety without a guard and retinue of servants. The roads, if they can be called such, are hardly-discernible tracks, quite unfitted for wheel-carriages, and travellers must therefore ride on horseback, or on the backs of elephants, or be carried in palanquins—a species of litter supported on men's shoulders. There being also no inns in India, each traveller is obliged to carry tents and provisions for daily use. In the states of Bhopaul, Oude, Gwalior, and the Company's possessions in the Doab, as well as in some other quarters, there exist hordes of wretches called Thugs, who infest the roads, and carry on a methodic system of murder, for the sake of plunder. They kill by strangling their unhappy victims. The Thugs form a peculiar race, and practise their murders, as is alleged, from a religious principle; at all events they attach no idea of criminality to the offence. They have practised the trade for centuries, and are with difficulty restrained within bounds by the European forces.

Independently of the efforts of the Bishop of India and the religious establishment with which he is connected, the Church of Scotland and other bodies of Christians have for some years been putting forth their exertions to attempt the conversion of the native pagan races, and consequently to elevate their condition. But on the whole, very little success has crowned their well-meant labours; the loss of caste, which inevitably follows the abandonment of the Hindoo faith, may be stated as a barrier to conversion which no power of persuasion can remove; in short, it has been proved beyond the possibility of doubt, that to Christianise India the people must in the first place be instructed in secular knowledge. Aware of this fact, attention is beginning to be directed to the education of the young. Fortunately, the general population throughout Bengal and Bahar, where investigations have been made, are zealously anxious for instruction in useful knowledge, as well as to learn the English language.

Until within the last few years, the intercourse with India was carried on by means of vessels belonging to the East India Company or private traders, which made the passage in about five months by the Atlantic and Cape of Good Hope. This most tedious route is still pursued by trading vessels; but the more expeditious route by the Mediterranean, Egypt, and Red Sea, to Bombay, is adopted for mail conveyance and passengers who desire a quick transit. The line pursued is across France to Marseilles; thence by steamboat, touching at Leghorn and Naples, to Malta; and by another steamer from Malta to Alexandria; or from Southampton direct by steamer to Alexandria; from Alexandria by canal to the Nile, and onwards by boat to Cairo; thence by land to Suez; down the Red Sea from Suez to Bombay, touching at Mocha—total length of time from London to Bombay from thirty-five to forty days!

The circulating medium of India consists of gold and silver coins, paper-money, and cowries. The most common silver currency is the new coinage of Calcutta. Potdars, or money-changers, are a common class in every town, and sit generally in the open air with heaps of cowries placed before them. Cowries are small shells, which, not being depreciable by imitation, form a good medium for buying and selling among the lower classes. Their value varies in different places. The following is their value in Calcutta:—4 cowries 1 gunda; 20 gundas 1 pon; 32 pons 1 current rupee, or 2s. sterling (2560 cowries); 10 current rupees £1 sterling. The sicca rupee is 16 per cent. less in value than the current rupee, which is an imaginary coin. The Bombay rupee is valued at 2s. 3d.; a pagoda is 8s. The British government now supplies a commodious coinage, the more common silver coin being the rupee, which nearly resembles our half-crown.

# AFRICA.

THIS is one of the great divisions of the globe—the second in point of size, but by far the least important as regards the civilisation and progress of the human species. It is situated in the eastern hemisphere, to the south of Europe, and the south-west of Asia, and lies between latitude 37° north, and 34° 50' south, and longitude 17° 30' west, and 51° 30' east. It is of an

irregular triangular form, with the vertex towards the south, having the Mediterranean on the north, the Isthmus of Suez, Red Sea, and Indian Ocean on the east, and the Atlantic on the west. It is thus almost entirely insular, the connecting isthmus being only 72 miles across, of no great elevation above the sea-level, and even in part occupied by salt-lakes and marahas.

The bounding coast-line is marked by few indentations or projections; the most important gulf being that of Guinea on the west; and Capes Bon, Verde, Good Hope, and Guardafui, the extreme points respectively on the north, west, south, and east. The greatest length of the continent, from north to south, is about 4985 miles; greatest breadth, from east to west, 4615; and area, including the islands, not less than 11,854,000 square miles.

### SUPERFICIAL FEATURES.

Respecting the physical aspect and construction of Africa, our information is extremely limited; all that is known, with any degree of accuracy, being parts of Morocco and Algiers in the north, certain points in the seaboard of Senegambia, Upper and Lower Guinea, Cape Colony, the hill country of Abyssinia, the valley of the Nile, and certain tracks or lines across the Sahara, or Great Desert. All description beyond these is mere conjecture, or the not very credible reports of natives and caravans. It would appear, however,

1st, That the triangular region south of the Kong, Cameroon, and Donga ranges, is a high dry table-land, hemmed in by mountains on all sides, and descending by steps to the sea-shore, which is in most parts rocky, and but partially fringed by narrow belts of sand. The bounding chains on the north rise, in the Cameroons, to a height of 13,000 feet, and probably much higher in the Dongas. Nothing is known of the Lupatas, or 'Backbone of the World,' on the east, save that they skirt, almost unbroken, the entire sea-coast; the hills of Cape Colony rise, from Table Mount, 3582 feet, to the Snieuveldt, 7400, and thence to the Nieuveldt, 10,000 feet, the intervening spaces being shrubby *kloofs*, or valleys, and broad grassy terraces, or *karoo*s. Cape Colony is, on the whole, an undulating country, enjoying a fine climate, by no means well-watered, and often subjected to destructive droughts. (See p. 278). Of the west coast, we learn that it is rather arid and sandy in the Namquas region; but, according to Dr Tams, the coast of Lower Guinea is generally rocky, and wooded

to the water's edge, unless at the river embouchures, and there it is composed of swampy impenetrable jungle.

2d, North of the Kong and Donga mountains, onwards to the frontiers of Morocco and Algiers, extend the great deserts of Sahara and Libya—constituting one vast plain, but little interrupted by undulations. This region presents three distinct series of aspects—namely, tracts of loose drifting sand, unrelieved by a single shrub; districts covered less or more with gravel and shingle, and bearing dry prickly shrubs, and a scanty herbage; and oases of light pulverulent soil, watered by springs, and studded with clumps of palms, dates, pomegranates, and other tropical trees. 'Instead of a torrid region,' says a writer in the Edinburgh Review, 'where boundless steppes of burning sand are abandoned to the roving horsemen of the Desert, and to beasts of prey, and where the last vestiges of Moorish civilisation expire long before the traveller arrives at Negroland and the savage communities of the interior, the Sahara is now ascertained to consist of a vast archipelago of oases; each of them peopled by a tribe of the Moorish race or its offshoots, more civilised, and more capable of receiving the lessons of civilisation, than the houseless Arabs of the Tell [the mountainous tract lying between the Great Desert and the sea]—cultivating the date-tree with application and ingenuity, inhabiting walled towns, living under a regular government, for the most part of a popular origin—carrying to some perfection certain branches of native manufactures, and keeping up an extensive system of commercial intercourse with the northern and central parts of the African continent, and from Mogador to Mecca, by the enterprise and activity of their caravans.'

3d, The mountainous district of the Tell, lying between the Desert and the Mediterranean—a region wholly composed of the Atlas chain, and its subordinate ridges. Where the hills fall towards the Atlantic in Morocco, the country becomes somewhat flat; but, eastward, it is hilly, and diversified only by narrow valleys and ravines. On the Mediterranean side of the elevation, the climate, produce, and aspect are somewhat similar to those of Southern Europe; but the other side is hot and arid, and insensibly passes into the Sahara. Mount Atlas attains an elevation of 11,400 feet, but some peaks in the chain rise much higher, and, according to recent accounts, seem to be permanently covered with snow—a fact which would seem to indicate an altitude above 15,000 feet.

4th, The region skirting the Red Sea, which comprises the hilly and not unfruitful countries of the Gallas and Abyssinians; Nubia, which, with the exception of the valley of the Nile, here comparatively narrow, is also hilly, and somewhat dry and arid; and Egypt, which consists of the alluvial valley and delta of the Nile, fenced on the west by low hills and desert, and on the east partly by the hills which skirt the Red Sea, and partly by the sandy desert which forms the Isthmus of Suez, and stretches onward into Arabia.

#### GEOLOGY—HYDROGRAPHY.

Respecting the *lithology* of Africa we know little, and that little only from observations made cursorily and at distant intervals. We know that the deltas of the Nile and Niger are formations recent and still in progress; and that the deserts of Sahara, Libya, and Egypt consist of sands, gravel, silicified woods, and other petrifications, which indicate a sea-bottom, upheaved at a very distant date. Granite, syenite, and porphyry abound in Abyssinia and Upper Egypt, and in Lower Egypt the nummulite limestone is the prevailing formation. Rocks of volcanic origin are abundant on the Red Sea, which seems still to be the seat of igneous forces. The Atlas range are chiefly granitic and primary; and sandstones of transition date were observed on the banks of the Niger during the model-farm expedition of 1841. In Cape Colony sandstones prevail, which seem to be transition or older secondary; and some specimens now before us, from Caffraria, are evi-

dently primary. Gold, silver, copper, lead, and iron seem to be plentiful, if we can regard the ornaments of the natives as evidence; indeed we have recent testimony, from an accredited explorer of the Russian government, that in the interior of Guinea auriferous sands are abundant, and apparently richer in produce than the deposits of Siberia. Natron has been long known to the inhabitants of the deserts, and salt, apparently collected from salt-lakes, forms an important article of commerce in the interior.

The *islands* connected with Africa are, with one exception, small, and generally far removed from the mainland. In the Indian Ocean are—Madagascar, separated from the continent by the channel of Mozambique, having an area of 230,000 square miles, or more than that of France, rich in mineral and vegetable produce, and with a population of 4,500,000; the important islands of Bourbon and Mauritius, each having an area between 800 and 900 square miles, with populations respectively 92,000 and 106,000, and fertile in every species of tropical produce; the minor groups of Comoro, Amerante, and Seychelles, north of Madagascar; and Socotra off Cape Guardafui, with an area of 1000 square miles, and a population of about 4400. In the Atlantic are—the volcanic group of Tristan da Cunha, occupied by a few British squatters; Ichaboe and other islets, along the south-west coast, recently ransacked for guano; the rocky islet of St Helena, 28 miles in circumference, and from 600 to 1200 feet high; the equally solitary volcanic rock of Ascension, recently garrisoned as a station for the slave cruisers; the densely-wooded isles of Annobon, St Thomas, and Fernando Po, in the Gulf of Guinea—the last rising in Clarence Peak to an altitude of 10,600 feet; the Cape Verdes, a rugged group of volcanic origin, rising in the still smouldering crater of Fogo to 7840 feet; the Canaries, consisting of seven principal islands, with an area of 136,000 square miles, and a population of 240,000, also of igneous origin, and rising in Teneriffe to an altitude of 12,182 feet; Madeira, 46 miles by 7, with a population of 113,000, composed of volcanic traps, which attain an elevation of 4400 feet, and celebrated for its delightful climate and wines; and lastly, the Azores, a numerous cluster, likewise of igneous birth, and rising in the Peak of Pico to 7000 feet, rich in tropical fruits and wines, with a population of 250,000.

Respecting the *hydrographical features* of the continent, little is known beyond the Nile and Niger; the existence of lakes Tchad and Dobbie in Soudan, Dembea in Abyssinia, and the salt-lakes of Tunisia. All that can be said of the rivers Zaire, Congo, Zambeza, Gaboon, &c. or of the lake Maravi, and so forth, is little better than conjecture. The Nile is valuable principally as the fertiliser of Egypt, as described in a subsequent section of the present sheet. By means of a recently-cut canal, it is open to flat-bottomed boats from the sea at Alexandria to Cairo, and from this to the cataracts by the rude shallops of the country. The Niger discharges itself, by upwards of twenty mouths, through a low accumulating delta, which greatly impairs its utility as a means of communication with the interior; nevertheless, during the late unfortunate expedition, the Albert steamer ascended with little difficulty to Egga—a distance of 350 miles from the sea.

#### CLIMATE—BOTANY AND ZOOLOGY.

The *climate*, as might be expected from the position of the continent, is wholly that of the torrid zone, with the exception of a belt on the north and the extreme southern projection. 'It may even be said that the influence of this tropical climate is felt over a great part of those countries which their northern situation should exempt from it; for it is really only that strip of Barbary which the Atlas protects from the hot winds of the Desert, and that part of Hottentot-land protected by the Nieuveltdt, and other mountains near the Cape, that enjoy the advantages of countries situate within the temperate zones. With the exception, therefore, of those small and narrow tracts, of those regions in the

## AFRICA.

interior to which their elevation imparts the coolness of higher latitudes, and the borders of the great lakes and rivers, every part of Africa is burnt up by continual heat, and the continent generally may be regarded as the warmest region of the globe. Nothing moderates the heat and the dryness but the annual rains, the sea winds, and the elevation of the soil; while in the well-watered regions, the moisture, combined with the heat, though productive of the most luxuriant vegetation, are extremely deleterious to man.\*

The *vegetation* of Africa, without raising any question as to what may have been introduced from other continents, is decidedly less varied, and more unique, than that of Europe or Asia. Along the Mediterranean seaboard it greatly resembles that of Southern Europe; and wheat, barley, maize, rice, the grape, orange, fig, olive, and date, thrive to perfection. In Upper Egypt, Nubia, and Abyssinia, the characteristic plants are gum-yielding acacias, the cassia or senna-shrub, coffee, ginger, turmeric, cardamoms, the lotus or jujub, and the nelumbium or water-lily. Cape Colony is distinguished for its heaths, proteas, pelargoniums, mesembryanthemums, stapelias, crasulæ, euphorbias, aloes, cactuses, thorn-apple, mimosa, and other prickly shrubs; and yields also luxuriantly such plants as have been introduced by the colonists—namely, vines, currant-grape, oranges, peaches, apricots, pears, apples, and other garden fruits known in the warmer parts of Europe, with tobacco, pine-apples, and tea, attempted by the Dutch. In the other known parts of the continent, the vegetation is strictly tropical, and often peculiar. Here flourish palms and dates, the banyan, gigantic adansonia, the dragon-tree, banana, papaw, tamarind, anona, sugar-cane, cotton-tree, cassava, tallow-tree, maize, manioc, yam, ground-nut, melon, pine-apple, and other forms native to warm regions; while in the islands are cultivated chiefly the vine, orange, melon, coffee, and sugar-cane.

The *Fauna*, as might be expected from the insulated nature of the continent, is in many instances peculiar; several of its forms being found in no other region. Among the more characteristic may be mentioned numerous apes and monkeys; the lion, panther, leopard, and other feline; the hyena, jackal, racoon, &c.; numerous species of antelopes and gazelles in the south; the buffalo, camel, dromedary, and giraffe; the horse, zebra, quagga; the elephant, rhinoceros, hippopotamus, and masked-boar; seals, dolphins, and other cetacea. *Birds*—eagles, griffons, vultures, and numerous birds of prey; the ostrich, bustard, and guinea-fowl; the parrot family in great abundance; the flamingo, pelican, secretary-bird, and crane; the cuckoo, swallow, nightingale, and quail, which are only summer visitors in Europe. *Of reptiles*—crocodiles, alligators, monitors, &c.; serpents in great variety, many of which are poisonous; lizards and chameleons; and various species of turtle. *Fish* are abundant in all the rivers and seas, and present forms unknown to Europe; crustaceans and shellfish are equally abundant. Africa possesses no useful insects, but has instead the locust, scorpion, termite, and scarabeus of ancient Egypt.

### POPULATION—INDUSTRY.

The *inhabitants*, vaguely estimated at 100,000,000, belong wholly to the *Æthiopic* and *Caucasian* varieties of our species: the former including all the dark-coloured native tribes, by whatever name they are called, from the Sahara and Abyssinia on the north to the southernmost extremity; the latter, the Egyptians or Copts, the Abyssinians, Arabs, Berbers, Moors, and other families arising from admixture of these. The *religion* of the negroes is Fetichism, or the worship of natural objects, animate or inanimate; the Arabs, Moors, &c. are Mohammedans; the Copts and Abyssinians observe a corrupted form of Christianity; and the European settlers are Roman Catholic or Protestant, according to the mother-country from which they come.

*Civilisation* is only to be met with in the settlements of the Europeans; the condition of the Moors, Arabs, and Egyptians, is scarcely entitled to rank higher than

that of semi-civilisation, while all the other native tribes are little in advance of the lowest barbarism. The arts are exercised only on the northern coasts, where the Moors manufacture silk, cotton, leather, and linen. An active commerce is carried on by them with the maritime nations of Europe; and by means of caravans, a traffic, fully as important, with the interior, to which they convey their own products and those of Europe. The wants of the savage races are exceedingly simple, and most of the articles used by them are prepared by themselves. Commerce, however, with Europeans has taught them new wants, and increased their list of necessaries; among which may now be reckoned firearms, powder, brandy, tobacco, different kinds of cloth, glass-beads, coral, &c.; for which they barter slaves, ivory, gold, gums, palm-oil, dates, and other raw produce.

### COUNTRIES—GOVERNMENTS.

The foreign powers having possessions in Africa are—*Britain*, occupying Cape Colony, which was taken from the Dutch in 1806; the Mauritius, with the minor islet-groups of Amerante and Seychelles, taken from the French in 1810; the islets of St Helena and Ascension; Fernando Po, all but abandoned; and the settlements of Sierra Leone and Cape Coast: *France*, possessing the island of Bourbon, the settlement of Senegambia, and, since 1830, the somewhat dubious and expensive colony of Algeria;\* *Portugal*, occupying some settlements on the Mozambique coast, the coast of Lower Guinea, and the west coast, the Cape Verde Islands, Madeira, and the Azores: *Spain*, to whom belongs the Canaries, and the forts or districts of Ceuta and Melilah, near the Straits of Gibraltar: the *Imam of Muscat*, who claims Socotra, and some portions of Zanzibar: and *Turkey*, who holds merely a nominal superiority over Tripoli, Tunis, and Egypt.

Respecting the native states and governments, we know little or nothing; and what little is known is of no civilised interest. In fact, with the exception of Egypt, which lays claim to high historical interest (see HISTORY OF ANCIENT NATIONS), as well as to some recent progressive movement under Mehemet Ali, and our own colony at Cape Good Hope, there is no region within the limits of the continent to which we need direct particular attention. To these two countries, however—the former as now forming the overland key to our Indian territories, and the latter as an emigration field of some importance—we may appropriately devote a few pages of description.

### EGYPT.

In point of local situation Egypt possesses various advantages. It lies in the north-east corner of Africa, in a salubrious part of that vast continent, presenting its northern base to the Mediterranean Sea, and bounded on the east by the Red Sea, which separates it from Asia. Through the whole land from north to south, a length of 900 miles, flows the Nile, a fine large stream rising in the inland kingdom of Abyssinia, and, from certain periodic floods, of great use in irrigating and fertilising the country. A large portion of Egypt consists of an alluvial plain, similar to our fertile meadow grounds, formed by the deposits of the river, and bounded by ranges of mountains on either side. The greatest breadth of the land is 150 miles, but generally it is much less, the mountain-ranges on either side often being not more than five to ten miles from the river. Anciently this territory was divided into three principal parts—Upper Egypt, which was in the inner or

\* 'The conquest of Algiers,' says Russel, in his account of the Barbary States, 'has relieved the Mediterranean from the dread of piracy, though it will be long before any other advantage can be derived from this achievement by France. The climate is indeed good, and the soil rich; but the inhabitants of the adjacent country are regardless of treaties, strangers to the enjoyment of social life, addicted to plunder, and accustomed to consider war as their hereditary profession.'

southern part; Middle Egypt; and Lower Egypt, which included what was called the Delta, a low district of land on the shores of the Mediterranean, formed by the mouths of the Nile into the shape of the Greek letter Δ, or delta. These divisions are still appropriate, forming an aggregate superficies of 202,000 miles, of which only about 20,000 are susceptible of profitable culture.

The Nile.

The most remarkable natural object in Egypt is the Nile, which periodically overflows its low banks, and inundates the greater part of the country. The Nile is formed by the union of two streams in the upper country, the Bahr-el-Abiad (white river), and the Bahr-el-Azrek (blue river), in latitude 15° 40' north. The former, rising in Abyssinia, to the south-west of lake Demben, comes from the south-east, and was considered by Bruce as the Nile. The latter, however, which comes from the south-west, and is supposed to rise in the Mountains of the Moon, in the centre of Africa, brings down the greatest mass of water, and is considered as the true Nile. There were anciently reckoned seven principal mouths by which the waters of the Nile were poured into the Mediterranean; only those of Damietta and Rosetta are at present navigable; the others have been silted up. The distance from the confluence of its two head branches to the sea is about 1500 miles; from its highest sources probably not far from 2500 miles. At certain points in its course the Nile falls over a series of cataracts, or, properly speaking, descends a series of tumultuous rapids, for the fall is nowhere above two feet of sheer descent. The cataracts are not altogether a bar to navigation, as flat-bottomed boats which sail up the river may be drawn up by an extraordinary force.

The grand phenomenon connected with the Nile is its annual overflow of the banks which border it—an event looked for with as much certainty as the daily rising of the sun. These valuable inundations are owing to the periodical rains which fall between the tropics. They begin in March, but have no effect upon the river until three months later. Towards the end of June it begins to rise, and continues rising at the rate of about four inches a day, until the end of September, when it falls for about the same period of time. Herodotus, the Grecian historian, informs us, that in his time a rise of sixteen cubits was sufficient to water the country. At present, twenty-two cubits are considered a good rise. The towns are generally built in such a situation and manner as not to be overflowed by the inundation; and in some parts of the country there are long raised causeways upon which the people may travel during the floods. It is only in cases of an extraordinary rise that any villages are destroyed. The inundations, instead of being viewed as a calamity, are considered a blessing, for they are the cause of inexhaustible fertility. After the waters have subsided, the earth is found covered with a fine fertilising mud, which has been left there by the river. The whole valley of the Nile may be considered as an alluvial plain composed of the washed-down mud and sand of Central Africa, and it is therefore to these inundations that Egypt owes its existence.

In Upper and Middle Egypt there are immense numbers of canals on the left bank of the river. Mehemet Ali, the late pacha, opened many of the old canals, which had been closed for centuries, and dug new ones; among the latter, the canal of Mahmoud, connecting the harbour of Alexandria with the Nile, near Fouah, 48 miles long, 90 feet broad, and 18 deep, is a magnificent work. The Delta is bordered by a number of maritime lakes or lagoons, which at different periods have undergone considerable changes; some of them had been dried up, when, from various causes, their connection with the ocean, which had been interrupted, was again resumed, and the exhausted basins replenished with water. It might be supposed, that in consequence of the annual inundations, Egypt would be a wet or moist country; but the

very reverse is the case. The waters are speedily dried up, and carried off as vapours by the winds, leaving the climate so remarkably dry, that meat in the open air will not putrefy, but be dried or shrivelled up. Rain, snow, thunder, or any of the common atmospheric phenomena, are seldom or never seen or heard.

Climate—Natural History.

In Egypt the harvests follow each other at the distance of about six or eight weeks, according to the different kinds of grain, leaving time in most cases for a succession of crops wherever there is a full command of water. The cold season commences with December, and continues for about two months. Early in February spring appears, when the atmosphere acquires a delightful warmth, and the trees put forth their blossoms. The period of summer may be said to commence in June, and to end at the close of September. The transition from the one season to the other is so imperceptible, that it is scarcely possible to say when the one begins and the other ends. During these four months the heat is intense; the fields to which the swelling river has not attained, are parched like a desert, and no green leaf is seen but such as are produced by artificial irrigation. Autumn, which is only marked by a slight diminution of temperature, commences about the middle of October, when the leaves fall, and the Nile retires within its channel; and till the approach of that season, which can only be called winter from its situation in the calendar, the face of the country resembles a beautiful and variegated meadow.

From the nature of the surface, and the universal aridity of the surrounding desert, Egypt is much hotter than most other countries under the same parallel. From March to November, the atmosphere is inflamed by a scorching sun and a cloudless sky, the average height of the thermometer being about 90°; during the other six months it is about 60°. At sunset, the winds fall, and the nights are generally cool, and the dews heavy. Except along the sea-shores, rain is a phenomenon in Egypt. At Cairo, there are on an average four or five showers in the year; in Upper Egypt, one or two at most; nor are they considered as beneficial to the agriculture of the country. Storms of thunder and lightning are still more uncommon.

In its geological features, Egypt presents great variety, including specimens of almost every formation, from the earliest to the most recent. Several granitic chains of hills stretch to a considerable extent. These contain vast quarries of syenite, from which the ancients drew the stupendous masses required for their colossal statues and obelisks. Between Assouan and Esna lies the sandstone, or middle district, which supplied blocks for the temples; and beyond it, the northern or calcareous district stretches to the southern angle of the Delta. This last chain supplied materials for the Pyramids, and many public buildings. The limestone extends from Syene to the Mediterranean, and, in Lower Egypt, from Alexandria to the Red Sea, in the vicinity of Suez. Other valuable rocks are abundant in Egypt, and various precious minerals are found.

Anciently, the country was more generally fertile than in the present day, owing to the encroachment of the sands of the adjacent deserts, and the long period of desolation and mismanagement in which it has existed. Still, owing to the inundations, the lands are more than usually productive, and yield crops of wheat, barley, rice, millet, maize, flax, beans, cotton, tobacco, the sugar-cane, and other useful vegetables. Of fruits, the citron, lemon, pomegranate, apricot, banana or plantain, and the palm-date, flourish luxuriantly. The palm is cultivated to a large extent in the inundated and irrigated lands, and groves of it, yielding a delightful shade, are to be seen, consisting of several thousand trees. Another celebrated production of Egypt is the lotus, a species of water-lily, of great beauty, exhibiting broad round leaves, amid which the flowers, in the form of cups, of bright white and azure, expand on the surface of the waters. The roots of vegetables were

used as food by the ancient Egyptians. There is also the papyrus, not less celebrated than the lotus, and which furnished a material used as paper, before the invention of that article; it is, like the lotus, an aquatic plant, growing to the height of eight or ten feet amid the swamps of the Nile.

In zoology, the camel, so emphatically named the ship of the desert, has long been domesticated in the country. The giraffe, or cameleopard, has been occasionally seen. Amongst the ancients, the ichneumon was venerated with a species of worship. Ichneumons are domesticated in Egypt, where they perform the duties of our domestic cat, in ridding the houses of the smaller animals. The names of the crocodile and hippopotamus are familiarly associated with Egypt and the Nile; but the latter is now rarely or ever seen below the cataracts. A species of lizard, called the monitor of the Nile; the common camelion; the lizard; the soxer, or shrew, and the jerboa; the goat, sheep, and the animals which figure in the Egyptian mythology, such as the dog, ape, buffalo, &c.—still belong to the zoology of the country. Of birds, the ostrich, the ibis, of which there are several species, and the Egyptian vulture, are most famous. With respect to fishes, the country presents nothing remarkable, with the exception perhaps of the polypterus or bony-pike of the Nile, the only existing analogue of a numerous division of fishes long since extinct, and now only found fossil in the transition and secondary formations of the geologist.

#### Inhabitants.

The population of Egypt is composed of an extraordinary mixture of races, and of all shades of colour; some claiming to be descendants of the ancient Egyptians, though utterly degenerated; others being from Arabian or Saracenic intruders; and so on to the number of a dozen distinct races; also a variety of mixtures to whom no name can be assigned. The following is the common enumeration:—1. The race called Copts, the supposed descendants of the ancient Egyptians, and more certainly the feeble remnant of a once numerous Christian population. 2. The Fellahs, who compose the bulk of the labouring class, and who are supposed to be a mixture of ancient Egyptians, Arabians, and Syrians; they are rigid Moslems. 3. The Bedouin Arabs, the same in character, manners, and customs that they are everywhere, and apparently ever have been since the days of the patriarchs. 4. Arabian Greeks; that is, the descendants of ancient Greek colonists, who have lost their ancient language, and speak a kind of Arabic. Many of them are mariners; but, in general, they pursue the inferior and handicraft trades. 5. Jews. To these must be added, as inhabitants of Egypt, 6. Syrian-Greeks and Maronites, who have, within the last century, greatly increased in numbers, and have proved successful rivals of the Copts and Jews as merchants and agents. 7. Armenians. 8. Turks. 9. Franks or Europeans. 10. Moggrelins, or Western Arabs. 11. Ethiopians, and other Africans. The following is as near an approximation as can be obtained of the relative numbers of the different divisions of this motley crew:—Copts, 160,000; Arab Fellahs, 2,250,000; Bedouin Arabs, 150,000; Arabian Greeks, 25,000; Jews, 20,000; Syrians, 20,000; Armenians, 10,000; Turks and Albanians, 20,000; Franks, 4,000; Ethiopians, &c. 7500; which amount in all to 2,666,500.

The Arabs have been divided into three classes:—First, the wild independent Bedouins, who occupy the Desert; second, the pastoral tribes, who feed their flocks upon the borders of Egypt, and occasionally enter the cultivated provinces; and lastly, the peasants or Fellahs, who are devoted to agriculture and the arts. The latter, who form the bulk of the population, are described as a fine race of men in their persons, active in agricultural employments, and possessed of many good qualities. In their dress and household economy in general, though not strangers to comfort, they are so to everything like luxury. Their food is very plain, and none but the higher

orders, or those of dissolute lives, ever taste wine. The Arabs carry on the common trades of civilized life, but in a very unskilful and imperfect manner.

After enumerating the various Oriental races who inhabit Egypt, it need hardly be mentioned that Mohammedanism is the prevailing religion. Generally speaking, those who profess Christianity know nothing of its doctrines or moral precepts, the practice of their faith being confined to a few unmeaning ceremonies, and the repetition of a few established phrases. The whole people, high and low, are in a state of intellectual darkness; in the towns there exist among Jews, Franks, and Turks, a degree of comfort and some wealth; but in the country parts many of the inhabitants are in a state of deplorable wretchedness; and in several districts they are seen almost entirely naked, having neither regular food nor clothing, and no lodging except in holes or mud-built hovels.

#### State of the Country—Mehemet Ali.

Mehemet or Mohammed Ali, the modern reformer and late pacha of Egypt,\* was born at Cavallo in Roumelia, a part of European Turkey. His parents, who were of a humble condition of life, had a family of sixteen children, of whom he was the youngest; and being a greater favourite than his brothers and sisters, he in early life became accustomed to indulgences, and to be impatient of the control of superiors. His youth, it has been related, was partly spent in the service of a tobacconist; but leaving this employment, which was unsuitable to his genius, he entered the Turkish army as a common soldier, at a time when troops were raising in his native district. This was the sphere of life in which he was calculated to shine. Distinguishing himself as a soldier by his bold and skilful conduct, he soon attracted the attention of beys, pachas, and the sultan himself; and having attained a prominent position in the bloody wars that distracted Egypt under the Mamelukes, he rose to be pacha, or viceroy, of Egypt, one of the highest posts of honour in the whole Turkish empire. On getting the command of that province, he speedily showed that he was no ordinary man. He established a regularly-paid, disciplined, and armed military force, on the European plan, instead of the irregular bands of men serving as soldiers in Egypt. The remnant of the Mamelukes, that remarkable body of men, which, since the days of Saladin, had practically governed Egypt by overawing the vice-regal authority, he annihilated, and thus became the uncontrolled lord of the land of the Pharaohs, Ptolemies, Cæsars, and Caliphs. By the strictness of his government, he rendered Egypt as safe to travellers as any ordinary civilized country. Agriculture, commerce, manufactures, all engaged his attention; and though his reforms were accomplished with a despotic hand, perhaps with no small degree of cruelty, still he prodigiously advanced the cause of civilisation and improvement in Egypt, and opened the way for further and more important reforms.

It is incontestable that Mehemet Ali did much to further the advancement of civilisation in modern Egypt; but the whole of his efforts at the same time tended to personal aggrandisement, and to the complete subjection of the people to his will. In order to maintain his authority, he raised troops from amongst the male population by the most tyrannical means; and so much was this forced military service detested, that great numbers of young men mutilated themselves, by destroying an eye, or cutting off one or more fingers, in order to escape the conscription. 'His revenue,' says Mr Lane, speaking of the pacha in 1836, 'is gene-

\* Mehemet, who is now at the advanced age of eighty-five, resigned in favour of his son Ibrahim, who was formally invested with the government of Egypt by the Turkish sultan in September 1848. Ibrahim, who has all along been the chief pride of his father, survived this elevation only for a few weeks—dying on the 10th November 1848 at the age of fifty-nine. Achmed, the son of a younger brother of Ibrahim, and grandson of Mehemet, is now viceroy and vizier of Egypt, acting of course in the spirit and under the influence of his grandfather.

rally said to amount to about £3,000,000 sterling. Nearly half arises from the direct taxes on land, and from indirect exactions from the fellahen (fellahs or agriculturists), the remainder principally from the custom-taxes, the tax on palm-trees, a kind of income-tax, and the sale of various productions of the land [no one being permitted to export corn or cotton but himself]; by which sale the government, in most instances, obtains a profit of more than 50 per cent. Mehemet Ali has increased his revenue to this amount by the most oppressive measures. He has dispossessed of their lands all the private proprietors throughout his dominions, allotting to each, as a partial compensation, a pension for life proportioned to the extent and quality of the land which belonged to him. The farmer has therefore nothing to leave to his children but his hut, and perhaps a few cattle and some small savings. The direct taxes on land are proportioned to the natural advantages of the soil. Their average amount is about 8s. per feddan, which is nearly equal to an English acre. But the cultivator can never calculate exactly the full amount of what the government will require of him: he suffers from indirect exactions of quantities (differing in different years, but always levied per feddan) of butter, honey, wax, wool, baskets of palm-leaves, ropes of the fibres of the palm-tree, and other commodities; he is also obliged to pay the hire of the camels which convey his grain to the government shooneh (or granary), and to defray various other expenses. A portion of the produce of his land is taken by the government, and sometimes the whole produce, at a fixed and fair price, which, however, in many parts of Egypt, is retained to make up for the debts of the insolvent peasants. The fellah, to supply the bare necessities of life, is often obliged to steal, and convey secretly to his hut, as much as he can of the produce of his land. He may either himself supply the seed for his land, or obtain it as a loan from the government; but in the latter case he seldom obtains a sufficient quantity; a considerable portion being generally stolen by the persons through whose hands it passes before he receives it. It would be scarcely possible for them to suffer more, and live. It may be hardly necessary, therefore, to add, that few of the fellahs engage with assiduity in the labours of agriculture, unless compelled to do so by their superiors. The pacha has not only taken possession of the lands of the private proprietors, but he has also thrown into his treasury a considerable proportion of the incomes of religious and charitable institutions, deeming their accumulated wealth superfluous. He first imposed a tax (of nearly half the amount of the regular land-tax) upon all land which had become a *wuckf* (or legacy unalienable by law) to any mosque, fountain, public school, &c.; and afterwards took absolute possession of such lands, granting certain annuities in lieu of them, for keeping in repair the respective buildings, and for the maintenance of those persons attached to them, as nazirs (or wardens), religious ministers, inferior servants, students, and other pensioners.' Mr Lane subsequently mentions that sometimes the poverty of parents causes them to sell their children to any one who will purchase them, which presents a shocking idea of the oppressed and degraded condition of the humble order of modern Egyptians.

In pursuing his schemes of improvement and family aggrandisement, Mehemet Ali acted as a despotic monopolist in all matters relating to both agriculture and commerce. He not only dictated what article of produce shall be cultivated, but the price at which it should be sold. According to Dr Bowring, it appears that in 1834, the country produced about 500,000 quarters of wheat, 450,000 quarters of dourah, 400,000 of beans, 280,000 of barley, and 80,000 of maize. Of wheat, however, the produce sometimes rises to 1,000,000 of quarters. The average price of wheat is from 20s. to 27s. per quarter at Cairo, but in years of scarcity it rises to 60s. Egypt is generally an exporting country, though sometimes, as in 1837, forced to draw supplies

from abroad. The cultivation of cotton was introduced by Mehemet, and succeeded well, the exports of this article in 1834 having been 200,000 cwts.; and in 1845, 18,000 tons. Flax-growing has also been revived, and exports to some extent have been annually made to Britain since 1839. The late pacha also endeavoured to extend the cultivation of sugar, introduced improved sugar-mills, and brought persons from the British colonies to distil rum. He also invited Armenians from Smyrna and the East Indies, to teach his people how to cultivate opium and indigo, and prepare them for the market. There are about 2,000,000 of date-trees in Egypt, each of which yields by its fruit from 8s. to 16s. per annum. A few attempts have been made to introduce the vine. Onions are still produced and consumed in prodigious quantities, as in the days of Herodotus. The pacha established model farms, with improved ploughs, pumping apparatus, &c.; but even his despotism could scarcely induce the people to abandon their ancient rude processes and implements.

The pacha was also a great manufacturer. He built large mills, and procured skilled workmen, at a great expense, from France, Italy, Germany, Belgium, and Britain, to conduct them. He had manufactories of cotton yarn and cotton cloth, woollens, carpets, iron-ware, muskets, cannon, bayonets, gunpowder, &c. which are still carried on by his successor. All these establishments are believed to have been attended with loss, and in some cases the loss was heavy. The spinning-mills for cotton were the most extensive of the manufactories. There were twenty-two of these in 1839, which, according to Dr Bowring, produced about 210,000 rottoli of yarn monthly, of various qualities, from coarse to 'very fine.' The Cairo rottoli is, we believe, just equal to the British pound, while the Alexandrian rather exceeds two pounds. The pacha had three manufactories of arms, which turned out 1600 muskets and bayonets per month. The largest one was managed by an Englishman, as indeed were most of the mills, factories, water-works, and other machinery. These and other innovations and improvements are still carried on with unsubdued ardour by Mehemet, whose retirement from office is rather nominal than real. He is still, though considerably upwards of fourscore, the centre and spirit of all reforming vitality and progress throughout the country: he maintains modern Egypt.

All travellers represent Mehemet as a person of plain and affable manners in private life, and fond of his family. Dr Bowring speaks of him as follows:—"Mehemet Ali was forty-six years old before he had learned either to read or to write. This he told me himself. I have heard that he was taught by his favourite wife. But he is fond of reading now; and one day, when I entered his divan unannounced, I found him quite alone, with his spectacles on, reading a Turkish volume, which he was much enjoying, while a considerable pile of books was by his side. "It is a pleasant relief," he said, "from public business; I was reading some amusing Turkish stories" (probably the Arabian Nights); "and now let us talk—what have you to tell me!" There is a great deal of sagacity in Mehemet Ali's conversation, particularly when he knows or discovers, as he usually does, the sort of information which his visitor is most able to give. He discourses with engineers about mechanical improvements—with military men on the art of war—with sea-officers on ship-building and naval manœuvres—with travellers on the countries they have visited—with politicians on public affairs. He very willingly talks of foreign countries, and princes and statesmen, and is in the habit of mingling in the conversation all sorts of anecdotes about himself, and the events connected with his history. His phrases are often poetical, and, like most Orientals, he frequently introduces proverbs and imagery. I heard him once say, speaking of the agriculture of Egypt, "When I came to this country, I only scratched it with a pin; I have now succeeded in cultivating it with a hoe; but soon I will have a plough passing over the whole land."

## AFRICA.

Oppressed as modern Egypt is, it is gratifying to reflect that it is improving in various respects. Education, after European models, has been introduced; and printing is now executed at Boulac, near Cairo, the press having there produced more than a hundred different books in the Arabic language, for the use of the military, naval, and civil servants of the government. A newspaper and an annual almanac are also regularly printed at Boulac. Another printing establishment has also been set down in Alexandria, and promises to be of vast service to the inhabitants, as well as to strangers and travellers. A considerable export and import trade is now carried on, the raw produce of the country being exchanged for the manufactured woollen, cotton, silk, and other goods of Europe. The cause of national regeneration is further advanced by the regular transit of European passengers on their overland route to and from India.

For administrative purposes, the country is divided into 24 departments, which are subdivided, according to the French system, into *arrondissements* and cantons. The capital is Cairo, an inland city, with a fluctuating population of 250,000. The chief ports are Alexandria, with a population of 60,000, Damietta and Rosetta on the Mediterranean side; and Suez and Cosseir on the Red Sea. The annual exports from Alexandria are estimated at £2,500,000; the imports at £3,000,000.

### CAPE COLONY.

The extreme southern projection of the African continent was formally taken possession of, in the name of Great Britain, in the beginning of the seventeenth century. No settlement, however, ensued this formality. In 1650, the district was colonised by the Dutch, who afterwards made settlements in Saldanha Bay and elsewhere; and disregarding, like other colonising adventurers, the rights of the natives, gradually extended their encroachments, till their territory reached nearly to the boundaries, of that now known by the name of *Cape Colony*. In 1795, the Cape was taken possession of by British forces; but at the peace of Amiens, in 1800, it was evacuated, and restored to its former masters. In 1806, it was again taken by the British, to whom it was finally ceded at the general peace in 1815. Since then considerable numbers of our countrymen—Scotch, English, and Irish—have made it their home; where, following chiefly a rural life, they rear herds, flocks, and corn; export wool, hides, horns, and ivory; and attempt the preparation of wine, tobacco, aloes, and some other drugs and dyestuffs. The aboriginal tribes consisted of Hottentots and Fingoes, Bushmen and Caffres, of whom the two former have become subject to the white settler, and been greatly reduced in numbers; while the latter have reluctantly retreated into the wilderness, contesting on the frontier whether barbarism or civilisation shall there prevail. The population of the colony—amounting to upwards of 160,000—consists, therefore, of our countrymen, of the Dutch boers or farmers, the subdued natives, and a number of half-castes—a motley community no doubt, but one which contains within it all the elements of steady and successful progress, if the nature of the country be such as will ultimately repay their exertions. The administration of public affairs is vested in a governor, aided by executive and legislative councils. In 1842, the gross revenue of the Cape amounted to £149,920, and the expenditure to £142,229; the last, however, was exclusive of the expenses incurred at home on account of the colony.

With respect to the eligibility of the Cape as an emigration field, numerous and contradictory opinions have been offered—interested parties describing it in unmeasured terms of approbation; while others, unsuccessful in their endeavours to settle, decry it as an arid and sterile waste. The following account, taken from 'Waterston's Encyclopædia of Commerce,' and the manuscript notes of an intelligent friend, who travelled the country in the early part of 1846, seem to contain

as fair and impartial a statement as it is possible to give within our narrow limits:—

'The Cape territory,' says the former of these authorities, writing in 1843, 'is in general rugged and barren, and deficient in the means both of internal and external communication. But a portion of the east coast is of a different character, more especially towards the north-east frontier, including the district of Albany, where the country is well-wooded and watered, and favourable for agriculture and grazing. The west coast, and a great portion of the rest of the country, consist of barren mountains and arid plains; one of which, the Great Karroo Desert, a high parched table-land, separating the Cape Town district from the finer country to the north-east, extends about 100 leagues in length from east to west, and 30 in breadth. The climate, however, is one of the finest in the world; and were the aridity of the soil counteracted by irrigation, and the means of intercourse improved by the formation of roads, the character of the country would be very different, as the capabilities of the soil are naturally great.

The only parts thickly settled are the Cape and Stellenbosch districts—which contain about 3-8ths of the whole population—some parts of Worcester, Graaf Reinet, and the British settlements at Graham Town and Bathurst in Albany; the other portions are occupied chiefly by the Dutch *boers*. Nearly 225,000 acres are under crop, yielding annually about 540,000 bushels of wheat, besides smaller quantities of barley, oats, and rye; the remainder of the productive surface is chiefly open pasture land. The principal mercantile commodity is wine, of which about 1,518,000 gallons are made yearly, besides about 126,630 gallons of brandy. The vine is grown chiefly in the Stellenbosch district, and within forty miles round Cape Town; but the wines, except that made at Constantia, near Table Mountain, are almost all of very low quality. Of late years, part of the capital which was embarked in the wine trade has been transferred to the production of wool, which has thus risen into considerable importance.

The progress of the Cape Colony has of late years been materially impeded by the invasion of the north-east frontier by the Caffres, and by the extraordinary emigration of about 20,000 of the Dutch colonists to Natal, on the east coast. The departure of the farmers has produced a rise in the price of provisions at Cape Town, which has materially lessened the demand for ship refreshments, formerly a principal branch of trade at that port, and amounting to about £100,000 yearly. The chief of the other native exports are—wine (1,000,000 gallons), wool, hides and skins, horns, tallow, flour, wheat, bran, butter, whale oil and fins, aloes, ivory, besides which, coffee, sugar, tea, spices, and a variety of other articles, are shipped at second-hand from Brazil, Mauritius, India, and China. In 1836 the exports amounted in value to £384,383; the imports into the colony in the same year amounted to £891,162, chiefly from the United Kingdom. With the exception of foreign spirits (principally brandy), wines, and spices, the British imports consist almost wholly of manufactured goods, and of these upwards of one-third are cottons; the remainder chiefly woollens, apparel, silks, arms, hardware and earthenware.

The ports are few and in bad condition. The principal are, Cape Town, the capital and seat of government, in Table Bay, population 20,000; Port Elizabeth, in Algoa Bay, the shipping place for the east part of the colony; and Simon's Town.'

'A single glance'—we turn to the notes of our travelling friend—'at Cape Colony, particularly in its eastern and northern districts, to any one acquainted with the nature of the vegetable world, would be sufficient to convince him that it is essentially a dry country, and little adapted for agricultural pursuits. As in many parts of Mexico and Peru, succulent plants (*Cactaceæ*, &c.) greatly abound, and are associated with a similar aridity of climate. Bulbs are also very plentiful, and, like the preceding, are fitted by nature to lay up a store of moisture, when it can be had, against the long

season of drought. This dryness of climate is at once the blessing and curse of Southern Africa. Upon it depend the purity and salubrity of the atmosphere; there are no fens or jungles of rank vegetation, on which the sun may act, and eliminate those noxious effluvia which generate the fevers and agues of damp unreclaimed countries under a similar parallel. But while an immediate advantage is thus gained by the emigrant on the score of health, he is healthy to little purpose, so far as his labours as a husbandman are concerned. He cannot commit his seed to the soil in the well-founded hope of seeing it in good time come to the sickle. Heaven denies him rain, and he must lead water: but this artificial supply also frequently fails, and all his field labour is lost. Or if his dams and fountains dry not up, then runs he the risk of blight or *rust*, which will often sweep over his crops, and hopelessly destroy them in a single night. And should he escape the rust, still the locust may come, and devour stalk and ear together. The latter pest is so multitudinously voracious, that I have known nine acres of maize, ready for gather, entirely eaten up in the course of a few hours. No doubt much more corn might be grown in the colony than is at present reared, and years of famine, by prudence and foresight, forestalled by years of plenty; still, so uncertain and precarious is the growth of grain—particularly of wheat—in most of the districts, that Cape Colony cannot now be reckoned, nor will ever likely become, an agricultural or grain-growing country.

Being essentially pastoral in its character, let us take a view at its capabilities in this respect. In general, from the scanty nature of the "sweet-grass" herbage—exclusive of its uncertainty by drought—one to four acres are required to depasture a single sheep, more than double that area for a horse, and nearly four times as much for an ox or cow. This estimate comprehends good and bad land indifferently over the entire area of a farm. The large extent of ground thus necessarily requisite for pastoral range has led to the practice of laying out the country into extensive farms, averaging from 6000 to 10,000 acres, or from nine to fifteen square miles. In many places it has been found impossible to apportion the whole land, even under such wide bounds, because of the want of water; and large tracts are still left out of occupancy from this cause. Families must consequently be kept far apart from each other, and this isolated condition proves a formidable bar to advanced civilisation. Even the villages in a country so divided, and without any mineral or manufacturing resources to form centres of population, must be few and far between—partaking of the character of mere trading posts between the distant farmer and merchant importer. The introduction of fresh blood and homogeneity from the mother country may improve, and has already done much for the tone of society; but left to itself and to natural influences, the pastoral population has no tendency to advance beyond the rude and simple condition of shepherds. The country has been long enough settled to have become a "States" or a "Canada," if nature had not put in her veto, imperatively gansaying such a consummation.

As a maritime country, its facilities are equally scanty and imperfect, compared with those of Britain and America. While these two countries are indented by numerous bays, gulfs, and inlets, Cape Colony presents a mural outline of coast, with scarcely an opening in it to admit a vessel to the interior, or a haven to give shelter from the seaward storms. There is not, in fact, a single navigable river opening on the coast, and no safe accessible harbour from Simon's Bay to Port Natal. Saldanha Bay, on the west coast, is the only complete haven possessed by the colony. This total inaptitude for inland navigation, and paucity of sea-board harbours, along a tempestuous coast, must ever operate as a check on commercial activity, and keep South Africa low in the scale of nations. At present, the want of roads also operates seriously against the success of the

settlers; but granting that this evil were remedied—which it is not likely soon to be—the absence of anything like ports must ever make the means of commercial interchange both insecure and expensive. I have seen imported goods, which were selling at thrice their average value, reduced to their usual price in the course of a few days, by the arrival of long-expected vessels; and as suddenly, on the other hand, the report of several wrecks raise these goods to the most enormous charges—thus bidding defiance to all the schemes and calculations of the inland farmer who had his far-brought produce to dispose of.

Another serious evil, and one under which its border population have groaned for years without remedy, is the encroachments and depredations to which they are constantly subjected in consequence of the naturally defenceless state of the northern frontier. The most troublesome and dangerous of the depredators have of late been the Gaika tribe of the Amakou Caffres, and the part of the colony subject to their harassing aggressions the eastern borders. The farmers in that neighbourhood, who may be justly reckoned the most enterprising in the colony, have from their first settlement experienced the unwelcome intrusions and vexatious pilferings of their lawless neighbours, who, issuing forth in little bands, like wolves in the night, have seized and carried off into Caffreland countless herds of colonial cattle. To such an extent has this habit of plunder been carried, and so bold have become the depredators, that an open war has been forced on the colony, as the only means left for the redress of its grievances. This is not the only time that the Cape has experienced the horrors of war, and had its borders ransacked by ruthless invaders; and there is little doubt, however severe and pregnant with suffering to the settlers the present conflict may be, that British arms will ultimately prevail.

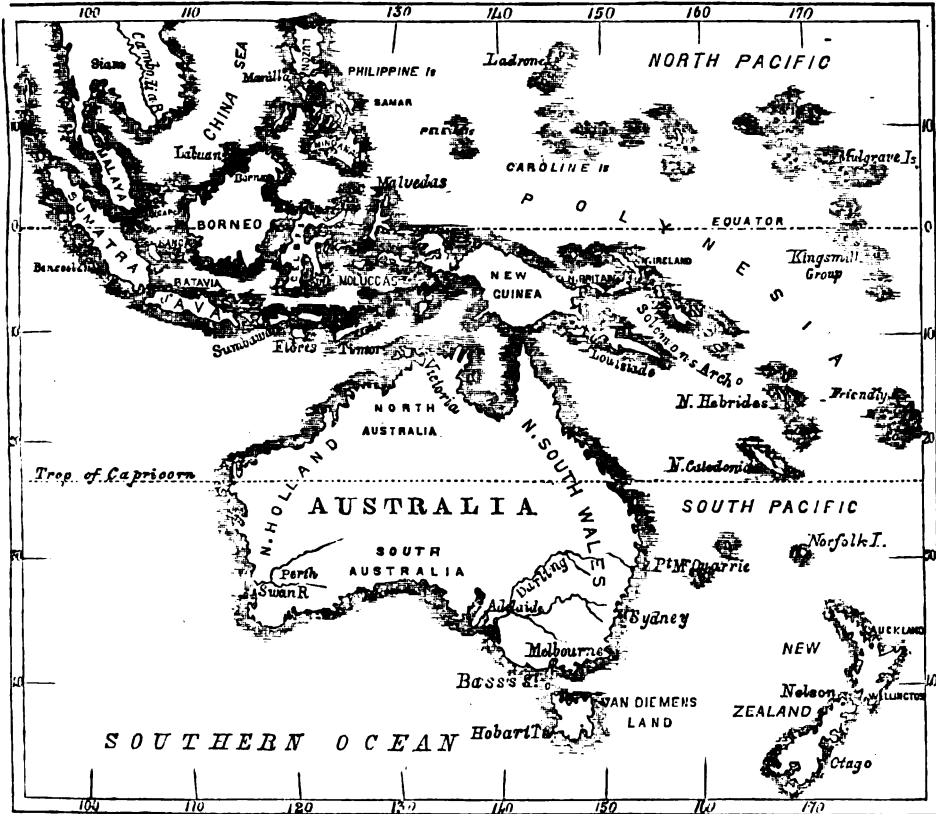

A general complaint throughout the colony is the scarcity of good servants: many things are left undone for which it offers abundant capabilities, from a deficiency of labour, as well as from the imperfect kind of labour to be found. Hottentots, Fingoes, and other coloured people, are the chief occupants of this walk, and are hired at from 5s. to 15s. a month, with rations. White servants are less numerous, and remunerated more highly—female domestics earning from £12 to £20 a year, and males from £18 to £30. All those introduced this season (1846) by the emigrant vessels from England have found places at such wages. But as these remarks lead insensibly into the advantages of the colony, I may now briefly allude to these.

He who can calmly contemplate and resolutely undertake expatriation from his native land, for the sake of an independence which its overcrowded walks of trade-craft deny, may realise in the Cape this desirable object. He is not foolishly to cherish high expectations either for himself or family; but if he condescend to look on himself and descendants as a nation of shepherds, and hazard those contingencies I have already noticed, most assuredly may he and his offspring enjoy the easy quiet life of such a race of men. Though not clothed in that freshness of verdure which renders home scenery so charming, the Cape possesses a much finer climate, a purer atmosphere, is not less salubrious, and yields abundance of all sorts of *fruits* found in the temperate zones, with many tropical ones in addition. But the leading advantage is its antithesis to Britain in its field of industry being unstocked: hence it is that no one in Africa need starve who is willing to use his hands, or can fail to find a profitable investment for capital, if he is cautious in its outlay. The farm-labourer will find his services eagerly sought after, and liberally paid; shepherds are in demand, and get from £30 to £40 a year; blacksmiths, masons, house and cabinet wrights, earn from 5s. to 7s. a day; indeed all sorts of labourers and mechanics will find employment and suitable pay, excluding those of course engaged in weaving, and other similar branches of industry, of which there is nothing of the sort in the colony.

# OCEANIA.

This term has been proposed by geographers to include the numerous islands scattered over the great ocean which extends from the south-eastern shores of Asia to the western coast of America. Oceania is separated from Asia by the Straits of Malacca, the Chinese Sea, and the Channel of Formosa; and from America by a broad belt of ocean, comparatively free of islands.

It may be said to extend from latitude 50° south to 30° north, and from longitude 96° east onward to 115° west in the opposite hemisphere. It naturally divides itself into three great sections—Malaysia, Australasia, and Polynesia—whose aggregate area has been vaguely estimated at 4,132,000 square miles, and population at from 14,000,000 to 16,000,000.

## MALAYSIA.

This division takes its name from the Malays, who are the principal inhabitants, and includes the archipelago immediately adjoining the south-eastern coasts of Asia, perhaps more generally known as the East India Islands. It lies between latitude 12° 40' south and 20° north, and longitude 95° and 134° east; and consists of minor clusters and chains, intersected by straits and channels, the intricacy of which would render the navigation dangerous, were not the seas distinguished beyond all others by their pacific character, and by the uniformity of the prevailing winds and currents. The whole of Malaysia lies within the tropics; and there is, accordingly, a great uniformity of climate, of animal and vegetable productions, and in the character of the people. The islands are, throughout, of a mountainous nature—the highest point being Mount Ophir in Sumatra, 13,050 feet; and the Archipelago is traversed by several lines of volcanic action, which exhibits itself in the burning craters of Luzon, Java, &c. There are few extensive plains, abundance of jungle and unhealthy swamp, but no arid deserts; and where not cultivated, the better land is generally covered with forests of stupendous trees.

The natural products may be gathered from a detail of the chief exports, which are, in the vegetable kingdom—nutmegs, cloves, cinnamon, pepper, coffee, rice, sago, indigo, cotton, sugar, flax, tobacco, camphor, cassava, maize, gums, gutta-percha, turpentine, betel, cocoa, ginger, canes, rattans, areca nuts, bamboo, breadfruit, teak, sandalwood, and other timber for building and cabinet-making; in the animal—ivory, wool, hides, horses, furs, pearls, edible birds'-nests, tortoise-shell, whale oil, sharks'-fins, ambergris, &c.; and in the mineral—gold-dust, tin, antimony, copper, iron, coal, diamonds, and other precious stones. Thus Malaysia is rich in every species of tropical produce, and, under a better system of rule, might be made one of the finest and most desirable regions in the globe.

The inhabitants belong to the Malay variety of the human species, but break into two or three races, having different depths of colour, straight, crisp, or woolly hair, and features less or more approaching those of the negro. They are generally arranged, according to their languages, into—Malays Proper, Javanese, Battaks, Bugis, Dyaks, Macassars, Sooloes, and other minor tribes. The foreigners or non-aborigines are chiefly Chinese, with a few Siamese, Hindoos, &c. from the

mainland of Asia. The religion professed by the Malays, Javanese, &c. is that of Islamism; Buddhism and Brahminism by the Chinese and Hindoos; Catholicism is practised by the Spanish and Portuguese subjects in the Philippines and Timor; Calvinism in the Dutch settlements; and polytheistic idolatry by almost all the independent tribes. There is nothing like education, and little deserving the name of civilisation in any part. Industrially, the growing of rice, cotton, coffee, &c. the gathering of raw produce, fishing, navigation, and, we may add, piracy, are the main employments in most of the islands.

As to government, the only civilised powers having possessions in Malaysia are the Dutch, Spaniards, and Portuguese. The Dutch possess or domineer over the whole of Java; the greater part of Sumatra, where they are continually extending their dominions; the Moluccas, or Spice Isles; and generally exercise a predominating influence over all the southern portion of the Archipelago. The Spaniards possess Luzon, and the greater part of the Philippine group; and the Portuguese retain only a portion of the island of Timor. During the last war, the British deprived the Dutch of Java and their possessions; but the whole were restored at the peace of 1815; and in 1825, Bencoolen, and the other British settlements in Sumatra, were exchanged with the Dutch for Malacca. Recently (December 1846) the small but apparently valuable island of Labuan, off Borneo, has been ceded to Britain, as a station for the India and China steamers; and important results are likely to arise from the procedure of Sir James Brooke at Sarawak in Borneo.

Britain has thus no direct political sway in Malaysia—a fact to be regretted, considering how little the European powers above-mentioned have done for the development—industrial or social—of these fine and fertile islands. Had they been retained in 1815, and the policy of Sir Stamford Raffles zealously carried out, this region would have now ranked next in importance to Hindoostan; for though less extensive, and more distant, it is equally fertile in every species of tropical produce, while its territories would have been preserved and governed with comparative little trouble or expenditure. It is true that Singapore is the great entrepôt for the produce of the surrounding islands, and thus in some measure British influence may be felt where it is not avowed; but until our merchants and traders have effected an absolute location, as is likely soon to be in Borneo, and until the machinery of a superior civilisation be brought to bear upon the natural capabilities of the soil, as well as upon the character of the natives, it is impossible to regard even the finest of these islands as other than misappropriated and neglected wastes.

#### AUSTRALASIA.

*Australasia*, the central and largest section of Oceania, is situated between the equator and 47° south, and longitude 112° and 180° east, and includes Australia or New Holland, Van Diemen's Land, New Zealand, Papua or New Guinea, New Britain and New Ireland, Solomon's Islands, New Hebrides, and New Caledonia. Australia is the chief island in the group, measuring 2400 miles from east to west, and 1700 from north to south. The physical character of this vast island or minor continent, so far as yet explored, seems very peculiar: with the exception of some hill-ranges, it is generally flat, or but slightly undulating; and in many places the inclination is inward instead of outwards to the sea. There being a general absence of high grounds, clouds are not attracted over the land, and there is thus a deficiency of rain; the rivers are for the most part a series of standing brackish pools, and of no value whatever as a means of internal communication. The plains or grassy flats are of vast extent, and being but partially studded with trees, afford the finest sheep-pasture in the world, when not parched by a long-continued dry season. The climate in the north is strictly tropical; in the southern colonised districts it is said to be

delightful—but liable to somewhat sudden changes, and occasionally to destructive droughts.

The native vegetation presents few features of interest—the most valuable being the australian or Norfolk pine; various species of eucalyptus, known as iron-bark, blue-gum, butted-gum, stringy-bark, &c.; the cedar and turpentine tree; varieties of causerina, as forest-oak, swamp-oak, &c.; the sassafras; curragong or cordage-tree; and others yielding gums, balsams, and manna. All the culinary vegetables and fruits introduced by the British colonists have flourished amazingly, and the settlements now enjoy every species of produce, from the vine, olive, pine-apple, &c. down to the humble gooseberry and raspberry of England. The original Fauna of the island is altogether anomalous: with the exception of the native dog or dingo, and a species of bat, all the quadrupeds are marsupial, or carry their young in pouches—the common forms being the kangaroo, wombat, opossum, &c. The ornithoryncus is another of its peculiar forms; as also the emu, lyre-pheasant, gigantic crane, black swan, bower-bird, and others. Reptiles are numerous, and some of them poisonous; fishes are rife along the coasts, as also whales and seals; shellfish, of beautiful colours and elegant forms, are everywhere to be found; and insects are prolific to a nuisance, the most useful being the native bees, which are stingless. All the common domesticated animals have been introduced; and these, especially sheep and oxen, have thriven amazingly. The geology of the country is very little known; but limestone, marble, bituminous coal, pottery-clay, iron, lead, and copper—the latter metal in particular—seem to be abundant in certain localities.

The aborigines appear to be a deteriorated offshoot from the Malay variety of our species; are in a state of utter barbarism; and seem destined to disappear before the white settlers, who are almost wholly British, with a sprinkling of Jews and Germans. The only European power having possessions in Australasia is Britain, to which belong Australia, Van Diemen's Land, New Zealand, and the penal settlement of Norfolk Island. The other islands are very little known, and wholly in the occupation of the native dark-coloured races.

The settlements or colonies are those of New South Wales, established in 1788; Western Australia in 1828; South Australia in 1834; and North Australia in 1838. The adjacent island of Tasmania, or *Van Diemen's Land* (which occupies 24,000 square miles, or somewhat less than Ireland), is the seat of another British colony, planted in 1824, and is altogether a thriving settlement—being more hilly and better watered than Australia. *New Zealand*, composed of three contiguous islands, ranging from 1100 miles in length, with a breadth varying from 5 to 200, is also the seat of a British colony planted in 1840. The soil is fertile, and capable of yielding every species of cultivated produce; the climate mild and equable; and the vegetable and mineral resources of prime importance. It is to these settlements that we would now specially direct attention:—

#### NEW SOUTH WALES.

This colony includes a large portion of the east side of Australia; the settled portions chiefly embracing the district within 200 miles of the east coast between Port Macquarie in latitude 31° 27' south, and the Muroo River in 36°; and the Port Philip district on the south coast. The general appearance of the east coast from the sea is far from being inviting, presenting immediately on the shore a continuous front of bold cliffs and mural precipices, unbroken for many miles together; behind these, again, and running generally parallel with them, at an average distance of about forty miles, rises a chain of rocky, precipitous, and almost impassable mountains, extending along the whole eastern coast. These are called the Blue Mountains. The unpromising appearance of the shores of New South Wales is not removed upon landing. For five or six miles interiorly the land continues barren and rocky, presenting few other signs of vegetation besides

some thinly-scattered stunted shrubs and dwarf under-wood. At this distance inward a marked change begins to take place; the soil improves, and begins now to be encumbered with tall and stately trees, which soon again thicken into a dense but magnificent forest, indicating, indeed, a more luxuriant soil than that passed, but scarcely less discouraging to the settler. Advancing inwards, however, from six to nine miles farther, another change takes place. You have cleared the forest, and the promised land lies before you, improving with every step you advance; now presenting an endless variety of hill and dale, covered with the most luxuriant vegetation; now extensive plains, resembling the finest parks in England—a resemblance which is made the more striking from their being similarly interspersed with magnificent trees, just numerous enough to add beauty to the land without encumbering it. The Port Philip district—the Australia Felix of Major Mitchell, who explored it in 1836—is altogether a finer country, less arid, more varied, and better wooded, but not so much so as materially to impede cultivation.

The government of New South Wales is conducted by a governor and a legislative and executive council: both of the two last, as well as the governor, are appointed by the ministry at home. The legislative council is composed principally of persons holding official situations, and these chiefly residing in the government towns. The executive council, again, is composed of persons filling the highest government appointments. There are, besides, a class of functionaries called police magistrates, distributed throughout the colony, and who take especial cognisance of offences committed by convicts, whom they have a power to punish by flogging or condemning to work in irons. Sydney is the chief seat of the colonial government, comprehending the supreme court, and the heads of all the civil and military establishments of the country. Being a colony of Great Britain, the laws by which New South Wales is governed are the same in their leading features with those of England, differing only in instances where such difference was found necessary to adapt them to the peculiarities of the country. Population, 190,000.

The external and domestic trade of New South Wales has scarcely yet emerged from a state of infancy; but it is fast gaining strength; and if no unforeseen circumstances should arise to check its prosperity, it will one day become, if it is not so even now, one of the most important of British settlements. Its leading export articles are wool, and seal and whale-oils; a great part of the latter is of that valuable kind called sperm-oil, produced by a description of whale found in the South Seas only. (See No. 44, Vol. I.) In the article of oil, which has only very lately become an object of serious consideration to the colonists, the improvement has been remarkably rapid, there being recently upwards of forty vessels, averaging a tonnage of nearly 10,000, belonging to, and sailing out of, Port Jackson alone, exclusively engaged in the whale-fishing. A striking evidence of the increasing prosperity of the colony, is the circumstance of its having in four years in some instances nearly, and in others more than doubled, the amount of its property in cattle and sheep, and also in the extent of its cultivated land.

We need not particularise the great and miscellaneous import and export trade of the colony, but confine ourselves to a few leading facts as an evidence of general prosperity. The imports, which amounted to £280,000 in 1826, had increased to £2,462,858 in 1841; whilst the exports from the colony, including the produce of the fisheries, had increased from £106,600 in the former year, to £2,004,385 in 1840. In 1824 the exports of wool amounted to 275,560 lbs.; in 1840 they were 9,668,960 lbs. In the Savings' Bank of New South Wales, the deposits increased from £24,469 in December 1835 to £127,000 in August 1840. In 1837 the revenue was £226,000; in 1841 it exceeded £270,000.

A large and profitable trade cannot fail to be ultimately established in wine, from vines which have been introduced as exotics. Already, from grapes grown in

the vineyards of the colony, excellent wine might be produced, if anything like good management were exercised. From the peaches of New South Wales the finest brandy is distilled: so superior is this article that, if it were allowed to be imported into Great Britain, it would speedily supersede the use of the brandies of France and other high-priced spirits. Silk (from the abundance of the mulberry) and dried fruits, with other useful and valuable articles, as opium and indigo, for the growth of which the climate is favourable, will doubtless by degrees be produced. At a short distance from Sydney, a large orange grove has been formed, from which upwards of 100,000 dozens of oranges have been sent into the market there in a year; and an immense quantity of fine grapes are sent by a steamer from Hunter's River every day in the season to the Sydney market. The only articles of food in general use not produced in the colony, are tea and sugar; but these are largely imported, and sold at perhaps not the third of their price in this country. In the advertisements in the Sydney newspapers, we see the same kinds of articles announced for sale by tradesmen as are seen everywhere in the wealthiest establishments in Britain.

The production of wool has for some time back been a primary consideration with the settlers, and they have of late begun to pay more attention to the quality than they did formerly, quantity alone having been at one time all they aimed at. From the improvement which has taken place in the breed of sheep, as well as in the mode of preparing the wool for the market, Australian wool has now become an object of much interest to the dealers and woollen manufacturers in England, where it is greatly prized for the peculiar softness of the cloth produced from it, and which, if combined with a little higher degree of fineness—a result that must soon follow the care and attention that is now bestowed on it—would place it on a level with the best growths of other countries, and consequently direct an inexhaustible stream of wealth into the colony; and there are two important considerations at this moment operating to produce this effect. The first of these is the readiness of the market, and the remunerating price which the settler obtains for his wool; the next, the necessity which the distance of the interior settlements from towns imposes on their occupants, of directing their whole attention to the rearing of cattle and sheep in preference to agricultural produce, for which there is neither facility of conveyance nor market.

The state of society in New South Wales has been to a considerable extent affected by the transportation thither of convicts from the United Kingdom, and on that account is less agreeable than that of colonies free from this moral stain. The most unhappy circumstance connected with the state of general society is, that the emancipated convicts and their descendants, however well behaved, are held as a degraded or inferior class by the free settlers; and thus two factions have sprung up in the colony, who virulently persecute each other, and cause dispeace in what would be otherwise an agreeable condition of affairs. As the settlement of convicts as labourers is abandoned as a practice unworthy of an enlightened government, it is to be hoped that the line of distinction between the two classes of inhabitants will gradually disappear. In Sydney, where society both bad and good equally flourishes, there are many hundreds of families of the highest respectability, enjoying all the elegancies of refined life, exchanging its courtesies, and cultivating its amusements and pleasures; splendid equipages are to be seen rolling along its streets; its public dancing and assembly rooms blazing with light, and filled, as our newspapers would say, with 'beauty and fashion;' music parties and theatricals filling up the measure of the happiness of a Sydney life. The population of Sydney in 1841 was about 30,000; and, as a commercial port, the exports exceeded £1,250,000. Next to Sydney, Bathurst has probably the highest pretensions to a superiority in the general character of its society. Melbourne, a few miles from Port Philip, is

also rapidly rising into importance. In 1842 its exports exceeded £140,000 (including about 2,000,000 lbs. wool), and its imports £336,000.

In New South Wales there are several infant schools, and about forty parochial schools; and also two government schools. An orphan hospital has been established at Sydney, capable of rearing and educating 125 children. The male children of this institution are apprenticed out as they come of age, and the females receive a small sum when married. The Australian College was established in 1831, and is now in a flourishing condition. By means of a large and regular import of English literature, the tone of feeling and general intellect of the colony cannot fail to advance in a yearly increasing ratio. With respect to the means adopted for sustaining religious and moral culture, we may mention that there is no lack of churches and chapels where they are required.

SOUTH AUSTRALIA.

South Australia is a large district of country, lying on the southern shore of the Australian continent, between the Swan River settlement or Western Australia on the west, and New South Wales on the east. It is contained within the 26th and 36th degrees of south latitude, and forms a territory of nearly 300,000 square miles, or 192,000,000 acres, being nearly double the dimensions of the British Isles. It is penetrated from the sea by Spencer's Gulf and Gulf St Vincent, at the entrance of which lies Kangaroo Island. The country from the eastern side of Gulf St Vincent is very picturesque; being in general well wooded, with considerable spaces of open country. This renders it admirably adapted for sheep-farming, and in many places the land is ready for the plough. About ten or twelve miles inland runs a range of hills, most of which are good soil to the top, and afford abundance of food for cattle. The highest of these is Mount Lofty, about 2400 feet above the level of the sea.

Gulf St Vincent is described as without an island, rock, reef, or sandbank, and almost any part of it is perfectly safe anchorage all the year round. Spencer's Gulf runs nearly 300 miles into the interior, becoming quite narrow and shallow at the top. It abounds with flat fish; but the country around is deficient in fresh water, and but a small portion of the soil is capable of cultivation. The great want of this colony is rivers, by which an intercourse with the interior could be effected. The largest river is the Murray, which is described by Mr James as being, for the last 200 miles of its course, nearly as broad as the Thames at London Bridge. On the banks of this river are several fine alluvial flats, at present covered with reeds, but which are capable of being made to yield abundant crops of grain. These flats are nearly on a level with the river, and could be irrigated at any season. The Murray delivers its waters into Lake Alexandrina, which also receives the waters of the Hindmarsh, and from thence to the sea the river is broad and deep. The next river is the Torrens, on the banks of which stands the town of Adelaide, the capital of the colony. The site of the town is well chosen as to the healthiness of the situation, but labours under the disadvantage of being six miles from the harbour, betwixt which and the town the carriage of goods is very expensive. The harbour is perfectly safe for shipping, but there is a bar at the entrance which prevents very large ships from entering. The great objection to the site of the town is the want of good water, which can only be obtained by boring to the depth of about forty feet, or taking it from the Torrens, which degenerates into almost stagnant pools in the dry season. The town of Adelaide has several good stone and brick houses, and the churches and public offices are described as handsome buildings. The river Glenelg, at the eastern boundary of the colony, is of considerable size during the winter months, but is almost dry in summer. Lake Victoria is a sheet of water about 20 miles long and 7 broad, communicating with the Murray River by a stream called the Rufus. Its banks

are well adapted for good pasturage, and the country around is well adapted for agricultural operations.

Much has been written upon the soil of South Australia. On the one hand, it has been lauded as the finest spot in the world, and on the other decried as not worth the trouble of cultivation. From the best authorities we have been able to consult, there appears to be very little of what can be called really barren land. The principal part of it is fit for grazing sheep and cattle, and there are many parts which would yield an abundant return of grain if subjected to the plough. From the want of mountains, the country is very free from rains; even the rivers become comparatively dry during summer. These deficiencies are, in fact, the grand drawbacks upon this otherwise fine colony, which is directed by a governor and council, much in the same way as New South Wales. The usual course of trade is similar to that at Port Philip; the population in 1842 was estimated at 16,000; the imports from Britain at £23,000; and the exports at £34,000. The whole of the purchase-money of public and waste lands being expended on the immigration of free labourers, and no convict labour permitted, South Australia offers certain advantages above New South Wales.

WESTERN AUSTRALIA.

This colony, which is entirely distinct from New South Wales, includes the settlements at Swan River, King George's Sound, and Port Grey. Swan River settlement takes its name, as is obvious, from the river in whose vicinity it is. This river is situated on the south-west coast of Australia, a little way north of the most extreme southern point, on the west side of the island. Its neighbourhood was first proposed as a place of settlement in the year 1828, when Captain Stirling was appointed lieutenant-governor.

The soil appears, and really is, until you have gone about fifteen or twenty miles inland, extremely poor and barren. At this distance from the coast, however, it greatly improves, exhibiting many beautiful and fertile tracts, and bearing some of the most magnificent trees in the world. Here, also, is the same profusion of those gorgeous flowers which form so remarkable a feature of the natural vegetable productions of New South Wales and Van Diemen's Land. Its animal productions are entirely similar to those of the two former colonies, and it is equally free from any that are dangerous to man. The heat, however, would appear to be more oppressive than in either of the places just named. The climate, however, is exceedingly salubrious. Not only have no complaints of any kind whatever, attributable to the country, appeared amongst the colonists, but they are enabled to bear exposures with impunity, which, in most other climates, might be attended with the most serious consequences. The best land, indeed the only land, yet discovered sufficiently near the settlement worth cultivating, is on the banks of the Swan River, and on those of an adjoining river called the Canning; but even there it rarely extends on either side more than two miles from the stream, and not often so far, and all this land has been already located. There is, however, reason to believe that good tracts of country are to be found in the interior. The pressure of emigration, and more leisure on the part of those already there, will no doubt very soon extend the dependencies of the settlement, and lead to some valuable acquisitions of country.

There are already several thriving little towns in the colony, amongst these Fremantle and Perth; the former the port, being built at the mouth of the Swan River, and the latter the capital. The site of Perth is represented as happily chosen. It is situated on a picturesque spot on the north bank of the river, about twelve or fifteen miles above Fremantle. At King George's Sound on the south coast are the lesser townships of Albany and Augusta. Latest statistics give the population at 4500; live-stock, 46,000; official value of imports about £1500; of exports, £24,000; revenue upwards of £10,000.

As to North Australia, whose only settlement is in the neighbourhood of Port Essington, too little has as yet been accomplished to afford ground for any definite opinion. As already remarked, the northern section of Australia is almost strictly tropical, thus presenting products and capabilities totally different from those to which our countrymen have been accustomed either at home or in the other colonies of the mother country.

## VAN DIEMEN'S LAND.

Van Diemen's Land, as already stated, is an island lying off the southern extremity of the mainland of Australia, from which it is separated by a channel 120 miles broad, called Bass's Strait. Its situation is between latitude  $41^{\circ}$  and  $44^{\circ}$  south, and between longitude  $144^{\circ} 40'$  and  $148^{\circ} 20'$  east. The length of the island is about 210 miles, and its breadth 150. It was first discovered in the year 1642 by Abel Jansen Tasman, a celebrated Dutch navigator, and was by him called Van Diemen's Land, in honour of Anthony Van Diemen, at that time governor-general of the Dutch possessions in the East Indies. Nothing, however, immediately resulted from this discovery, and for upwards of a hundred years the island was lost sight of. In 1773 it was visited by Captain Furneau, the first English navigator who had ever touched at it; after this it was visited from time to time by several celebrated navigators, and amongst these by Captain Cook, in the year 1777. It was not, however, until 1803 that any settlement was made upon the island; in that year it was formally taken possession of by Lieutenant Bowen, as a receptacle for convicts, with a party from Port Jackson, in New South Wales, where a penal establishment had been already fixed; and to this purpose Van Diemen's Land was exclusively devoted until 1819, when it was thrown open to free settlers.

The continent of Australia and Van Diemen's Land are totally different in character, the one being flat and ill-watered, so as to be suitable chiefly for pasturing, while the other is mountainous, and more resembling Ireland or Scotland. The appearance of Van Diemen's Land from the sea is exceedingly picturesque, presenting an endless succession of lofty mountains, covered to their summits with wood; while tall rocks and precipices, glens and hills, contribute to increase the interest of this romantic island. Nor does a nearer inspection materially alter this general character of the scene. On traversing the island, it is found to present a constant alternation of hill and dale, with occasional flats or plains; but these are comparatively few in number, though some of them are of great extent, consisting in several instances of not less than from 8000 to 10,000 acres, and one in particular is said to be 6 miles in length, and from 2 to 3 in breadth. These plains are in general exceedingly fertile, and being often but thinly interspersed with trees, present a most delightful appearance. There are some of them, again, very poor, presenting a cold thin soil of little value. Van Diemen's Land, though it cannot be called a well-watered country, is yet much superior in this respect to New South Wales.

In another important particular this island is peculiarly fortunate—that is, in the number and capacity of its harbours, no place of similar extent in the world probably being equal to it in this respect. The principal harbours are—the Derwent on its southern side, Port Davey and Macquarrie Harbour on the western, Port Sorrel and Port Dalrymple on the northern, and Oyster Bay and Great Swan Port on the eastern coast. Besides these, there are many other harbours, bays, and creeks, distributed all amongst its shores. The coast is in general high and rocky, particularly on the south, east, and western sides of the island: on the north, however, it presents a line of low alternate sandy beaches, on which the surf rolls with great impetuosity during the prevalence of northerly winds. From the extremely hilly nature of the country, there is but a comparatively small proportion of it adapted for the plough, though presenting abundance of excellent pas-

ture. The extent of really available land throughout the island has been estimated at one-third of the whole, and this is again divided into four parts, giving one for the plough, and the other three for pasture: thus out of 1000 acres of land, about 100 will be found fit for cultivation, and from 300 to 400 for grazing.

The climate of Van Diemen's Land is exceedingly pleasant and salubrious, and is especially adapted to the constitutions of the natives of Great Britain: the heat in summer is not so intense as that of Australia, not often much surpassing that of London or the southern parts of England; while the mornings and evenings, even at the hottest periods of the year, are always cool and agreeable. The cold in winter, however, though mild when compared to what we experience at that season, is more intense and of longer duration than that of Australia, snow lying frequently on the higher mountains throughout the greater part of the year; but in the valleys and lower districts it seldom remains more than a few hours. There have not yet appeared any diseases which can be said to be peculiar either to the climate or to the island; and, on the whole, the chances of life are estimated to be considerably more in favour of Van Diemen's Land than of Britain, or any other of the most healthy parts of Europe. It is not subject to any extremes of heat or cold: the seasons are regular, mild, and agreeable; the atmosphere constantly pure and elastic; and the sky clear, unclouded, and brilliant.

The island possesses a considerable variety of trees and shrubs. The gum-tree is the largest; and there are numerous others well adapted for ship and house building. The trees are all tall and straight, branching only at the top, and they are nearly all evergreens. All the vegetables and fruits known and cultivated in England and Scotland are raised without difficulty—apples, pears, plums, gooseberries, &c. to which the warmer temperature of Australia is unfavourable, are produced here in great abundance, and of excellent quality. Both the climate and the soil are sufficiently favourable to the production of most descriptions of grain; wheat is found to thrive remarkably well; potatoes are in general a good crop, and of excellent quality. The island is altogether, in short, fit for all the purposes of agriculture aimed at in this country, being neither more nor less favourable to them, but in all respects nearly the same; its climate being ours, only somewhat modified, and its soil in general not materially differing in quality. In July, August, and September, which are the spring months, the farmer sows his grain; in October he prepares the land for Swedish turnips; in November he gets in his potato and turnip crops; December is the height of his hay harvest; at about the middle of January his wheat harvest commences, and continues through February; in March he pays attention to his fallowing and husbandry; in April he gathers his second crop of potatoes; in May he lays down his grasses; and in June he continues his ploughing and harrowing. He has thus a continual round of pleasurable occupation in his fields.

Till the year 1825, Van Diemen's Land was a dependency of the colony of New South Wales, but in that year it received a government of its own. The internal policy of the island is now conducted by a lieutenant-governor, and an executive and legislative council. There are also here a chief-justice, attorney-general, and all the other appendages of a supreme court of judicature, courts of requests, attorneys, barristers, solicitors, proctors, sheriffs, justices of the peace, and the whole paraphernalia of civil and criminal jurisprudence known in this country. There are, besides, as in New South Wales, a number of police magistrates, each having a separate district under his judicial authority; these are, as in the former case, stipendiary. The laws are the same with those in England, in as far as the circumstances of the colony will admit.

Society in Van Diemen's Land, like that of New South Wales, is made up of free settlers who have emigrated from this country, and of convicts. There

are no aborigines now in Van Diemen's Land, these having been lately conveyed to an island in Bass's Strait, and an order has been issued by the home government for their removal to Port Philip district, New South Wales. Regarding the bush-rangers, or runaway convicts, from the effective police force kept up, their depredations are confined to the less-populated districts, and even there they seldom exist long without being captured.

The capital of the colony is Hobart Town, situated on the left bank of the river Derwent, at the head of a beautiful bay, distant about twenty miles from its junction with the sea. The town is pleasantly situated on a gently rising ground, which, gradually retiring, terminates ultimately in hills of considerable height, covered with wood, and presenting a most romantic appearance. These again are overlooked by one of still greater altitude, called Mount Wellington, which rises to the height of 4000 feet above the level of the sea. Hobart Town is thus happily placed between highly-picturesque hills on the one hand, and a beautiful bay or arm of the sea on the other; for, though the Derwent be here called a river, it can be so called only in a very extended sense, the water being still salt, and of considerable width. The town itself covers somewhat more than a square mile of ground; the houses are principally constructed of wood, though many of them are of brick and freestone. The streets are regularly laid out, and those of them that have been completed are macadamised, and present on either side long rows of large and handsome shops. The town derives a peculiar and highly pleasing character too from the circumstance of the houses in general standing apart from each other, each having a small plot of ground, from a quarter to half an acre in extent, attached to it. Its public buildings are numerous, and many of them would be considered handsome even in Britain. The town contains breweries, tanneries, distilleries, flour-mills, two or three banks, hospitals, churches, schools, charitable and stipendiary, inns, taverns, hotels, and grog-shops *ad infinitum*, and everything else which bespeaks a thriving, bustling, industrious, and civilised community.

The town next in importance to the capital is Launceston, situated at the junction of the North and South Esk, at the head of the navigable portion of the river Tamar, which discharges itself into Bass's Strait, about forty-five miles below the town. The town presents a very business-like appearance, with its shipping, wharfs, stores, and public buildings, all calculated to impress the stranger even on a cursory glance with a high idea of its rising importance. From the favourable nature of its situation for commercial purposes, the river being navigable for vessels of 500 tons burthen up to the town, the trade of Launceston is very considerable, and is every day increasing.

The population of the colony in 1842 was estimated at 50,216; but must now be considerably increased, both from the natural progress of population, and the influx of additional immigrants. In 1839, the land-sales amounted to 42,886 acres, at the average of 10s. 2d.; and in 1840 to 86,296 acres, at 11s. 4d., exclusive of town lots and military grants. The principal exports are wheat, wool (in 1841, 3,597,531 lbs.), whale-oil, bark, &c. amounting in 1840 to £867,000; and the imports, comprising all kinds of British manufactures, colonial products, spirits, wines, farming implements, &c. to £988,356. In 1842 the official value of exports to the United Kingdom was £134,150; and that of the imports from the United Kingdom £260,730. At present the annual revenue of the colony is about £100,000, and the expenditure about £138,000. The leading, if not the only misfortune under which Van Diemen's Land labours, is a deficiency of good roads.

#### NEW ZEALAND.

New Zealand consists mainly of two large islands, called the Middle Island and the North Island, separated by a passage called Cook's Straits, with numerous

smaller isles scattered around their shores. They lie in the great southern ocean in an easterly direction from Australia, and at a distance of about 1200 miles from that continent. The New Zealand islands are situated between the 34th and 48th degrees of south latitude, and the 166th and 179th of east longitude. The Middle Island is about 500 miles long, and from 100 to 120 broad. The northern island is the smaller, being about 400 miles long, and from 5 to 30 broad; both being estimated to contain nearly 95,000 square miles, of which two-thirds are fit for cultivation. New Zealand was first discovered in 1642 by Tasman, who, however, did not land, supposing it to form a part of the southern continent. Captain Cook first sailed round the islands, and surveyed their shores with so much accuracy, that his charts are depended upon even to the present day. The distance of New Zealand from Great Britain is rather more than to New South Wales, or about 16,000 miles, but is reached by the same line of voyage round the Cape of Good Hope, the return being by Cape Horn. Vessels reach New Zealand from Sydney in ten or twelve days.

New Zealand is evidently of volcanic origin, there being many extinct and a few active volcanoes in the interior of the islands. Hot springs have also been found, some of which are described as higher than boiling heat, and most of them of a sufficient temperature to cook any kind of native food. A chain of mountains runs through the whole of the southern, and a considerable part of the northern island. Some of these mountains are as high as 14,000 feet above the level of the sea, their tops being covered with perpetual snow, and their sides with forest-trees and luxuriant ferns. Besides this chain of mountains, there are other subordinate ranges, which, for the most part, are covered with vegetation to the summit.

There are numbers of fine streams and rivers scattered throughout the country, which have their origin in these mountains. Several of the rivers are navigable to a small extent, and possess waterfalls which afford the means of establishing mills in most parts of the country. From the shape of the islands, and the mountains which intersect them, the rivers do not run to any great length, from 100 to 200 miles being the average. In 1838, the ship Pelorus entered a river in the southern island falling into Cook's Straits, and sailed up more than 30 miles, and her boats continued the navigation for 20 miles farther. The river Hokianga, in the northern island, situated almost opposite the Bay of Islands, has been navigated 30 miles by vessels of 500 tons burthen. Another river, the Haritoua, which falls into Port Nicholson, is said to be navigable for a considerable distance inland.

The bays and harbours of New Zealand are not surpassed either in number or advantages by those of any country in the world. Beginning with the North Island, we have first the harbour of Wangaroo, the entrance to which is narrow; but inside, the harbour is spacious and well-sheltered. The Bay of Islands is about 25 miles south of Wangaroo, and is the harbour which has been hitherto most frequented by Europeans. The entrance to the bay is 11 miles broad, and perfectly safe, there being no bar. Inside, the bay is studded with a number of rocky islands; the water is deep close to the shore, and the anchorage is excellent. To the south of the Bay of Islands is the Firth of the Thames, which contains several well-protected harbours. The tide flows in this firth to the height of from 8 to 10 feet, and at all times there is plenty of water for ships of almost any tonnage. The Bay of Plenty, on the north-east coast, is formed by the island becoming much broader in a curved direction. This bay is very large, and possesses an excellent harbour called Tauranga, which is much frequented for the shipment of flax, &c. Hawke's Bay is very extensive and deep, the soundings showing from 6 to 27 fathoms water. The most important harbour in the northern island is Port Nicholson, situated in Cook's Straits. The bay is about 12 miles long and 3 broad, perfectly sheltered, and ships may enter or leave

with any wind. The depth of water is from 7 to 11 fathoms, and the whole bay is described as of sufficient capacity to hold a navy. Port Nicholson has the disadvantage of being upon a lee shore, but this objection can only have weight with regard to the navigation of Cook's Straits, not to vessels lying in the port itself. On the west coast of the North Island the harbours have generally a bar at the entrance, which render their navigation more dangerous than those on the east coast. The best harbour on the west coast is that of Hokianga. It receives the river of the same name, and a number of smaller streams; and from all accounts it seems to be a valuable district for settlement. There is a bar at the entrance with 3 fathoms water at low ebb; but the tide rises 12 feet, and inside the harbour deepens to 17 fathoms. To the south of Hokianga occurs the harbour of Kaipara, which is 30 miles long, and receives the waters of three considerable streams.

In the middle island, within Cook's Straits, is the fine harbour of Queen Charlotte's Sound, which is nearly 30 miles long. Ship Cove, within this sound, is a very fine harbour, to which European vessels have long repaired, in consequence of its having been described by Captain Cook. The harbour is perfectly sheltered, and the soundings show 10 fathoms a cable's length from the shore. At the north-western extremity of this island is Cloudy Bay, which runs 15 miles inland, and is about 4 miles broad. Besides these two harbours, there are many others in the island, such as Lookers-on Bay, Port Gore, and Blind Bay; all affording facilities for roadsteads and harbours.

From the position of New Zealand being north and south, it presents great variety of climate considering the size of the country. All accounts agree, however, in describing it as highly salubrious, and very congenial to European constitutions. Spring commences in the middle of August; summer in December; autumn in March; and winter in July. During winter the temperature ranges from 40° to 50° in some parts, and in others the average is higher. In summer the thermometer ranges from 64° to 80°, which is the highest temperature given. Mr Yate, in his Account of New Zealand, speaking of the climate, says—'Those who come here sickly are soon restored to health; the healthy become robust, and the robust fat. North of the Thames snows are unknown; and frosts are off the ground by nine o'clock in the morning. The country, during six months in the year, is subject to heavy gales from the east and north-east, which generally last for three days, and are accompanied with heavy falls of rain. In the winter season the moon rarely either changes or waxes without raising one of these tempestuous gales; and during the whole year the wind is sure to blow, though it may be only for a few hours, from the east, every full and change of the moon. The spring and autumn are delightfully temperate, but subject to showers from the west-south-west. Indeed, however fine the summer may be, we are frequently visited by refreshing rains, which give a peculiar richness to the vegetation and fertility of the land. The prevailing winds are from the south-west and north-west, which, within this range, blow upwards of nine months in the year; more frequently the wind is due west. During five months sea-breezes set in from either coast, and meet each other half way across the island.' The climate of New Zealand has one great advantage over that of Australia, in not being subject to the severe droughts which so often destroy the hopes of the farmer in that country. Its insular position, and the lofty mountains which intersect the country, insure it a constant supply of rain. This circumstance gives it a decided superiority over Australia in an agricultural point of view, rendering it more suitable for the growth of grain; though we are not aware of its being greatly superior to Van Diemen's Land. It does not appear that there are any diseases peculiar to the climate of New Zealand: all accounts agree in describing the inhabitants as a robust and healthy-looking people. Captain Cook says he never saw a single person among

them who appeared to have any bodily complaint; and their wounds healed with astonishing rapidity.

The soil of New Zealand appears in almost every part to be excellent, well adapted for cultivating all sorts of grain, and indeed most European vegetables. Around the mountains the soil is volcanic, somewhat resembling that of some parts of Italy. In other parts it appears to be a fine stiff loam and vegetable mould, very productive. Captain Cook, describing the valleys, says—'The soil in these valleys and in the plains, of which there are many that are not overgrown with wood, is in general light but fertile; and in the opinion of Mr Banks and Dr Solander, as well as of every other gentleman on board, every kind of European grain, plant, and fruit, would flourish here in the utmost luxuriance.' The natives cultivate the potato in considerable quantities, which yields them a good crop without much trouble. There is also plenty of fine open land, consisting of alluvial soil deposited from the mountains, which would yield abundant crops of wheat, maize, barley, and other grains. In other parts the soil consists of a deep stiff vegetable mould on a marly subsoil, capable of being slaked with the ashes of the fern. Mr Yate says—'All English grasses flourish well, but the white clover never seeds; and where the fern has been destroyed, a strong native grass, something of the nature of the Canary grass, grows in its place, and effectually prevents the fern from springing up again. Every diversity of European fruit and vegetable flourishes in New Zealand.'

The forest-trees grow to a very great size, many of them being larger than those of America or any country in the world—a sure proof of the fertility of the soil. The largest tree is that called the *kauri*, belonging to the pine tribe. It grows in some cases to the height of eighty or ninety feet without branching, and the branches themselves may be compared to ordinary trees. The trunk is of immense girth, and the wood tough and light, being admirably adapted for ship-building, or almost any other purpose. Another tree, called the *totara*, reaches a height of from fifty to sixty feet, and a circumference of twenty feet. Its wood is very hard, of a red colour, works easily, and from its size and strength may be applied to many useful purposes. The *pariri*, or New Zealand oak, is a tree of great hardness and durability, the wood being of a dark-brown colour, and capable of taking on a beautiful polish. It has been known to remain twenty years under ground, in a wet soil, without rotting. The *farairi*, a tree of the laurel tribe, reaches the great height of from fifty to seventy feet, while its diameter is not more than three feet. It has a very beautiful appearance, and is one of the chief ornaments of the woods, but does not appear to be applied to any useful purpose. Besides these, there are many other trees in New Zealand, especially the pines, which are said to afford very superior timber for ship and house building, and also furniture-making.

The *Phormium tenax*, or New Zealand flax, is another important vegetable production, which is likely to form an article of considerable export. It is said to resemble the garden iris in appearance, having a green thick leaf from six to ten feet long, and growing in the greatest luxuriance throughout the country. The fibres of the leaf of this plant are used for making ropes, and many competent judges state that it is better adapted for this purpose than the European flax. Mr Ward thus sums up his account of the vegetable productions:—'New Zealand is fitted by nature for the production in abundance of those three articles which have always been regarded as the especial signs of the plenty, wealth, and luxury of the country—corn, wine, and oil. Its fertile plains adapt it to the easy cultivation of grain, for the surplus production of which it will possess a ready market, from its vicinity to New South Wales and Van Diemen's Land, where, from the high profits of wool-growing, grain from foreign countries will always find a ready demand. The vine has also been tried, and found to thrive luxuriantly in both islands.'

The very circumstance of New Zealand being suited for the cultivation of grain, renders it unfit for ever becoming an extensive grazing country, at least for the growth of the fine wools of Australia. The following remarks from the Sydney Herald newspaper were written by a person who had visited New Zealand on seven different occasions:—'New Zealand is fitted by nature to become the garden of New South Wales: the fertility of the soil, the excellence of the climate, and, above all, the regularity of the seasons, eminently combine to fit it for an agricultural country. But it is only as an agricultural settlement that New Zealand can flourish; as a pastoral country, it can never compete with New South Wales. The experiment has again and again been tried, and the result has invariably been the same. The climate is too moist for sheep pastures; and the fine wool for which New South Wales is so remarkable, speedily deteriorates in quality on the transportation of the sheep to New Zealand.'

Little definite is known of the mineral productions of New Zealand. Iron and coal are found in abundance, along with bitumen, freestone, marble, sulphur, and copper. A blue pigment made use of by the natives is said to be manganese, and there is a valuable green stone (nephrite) found exclusively in the middle island, which, when polished, excels in beauty many of our finer marbles. There is also abundance of clay fit for brick-making and earthenware.

There are no native quadrupeds in New Zealand, those at present existing having been left by Captain Cook and other Europeans during their visits to the islands. Pigs are numerous, having spread very rapidly throughout the country. They are said to grow to an enormous size, and are highly valued by the natives. Dogs abound, especially about the Bay of Islands; and cats are also plentiful, and are eaten by the natives. The cattle which have been introduced by the missionaries are said to thrive well. Sheep have also been tried, and in some open parts succeeded; but New Zealand, as already stated, is more of an agricultural than a pastoral country. The only reptile yet seen in the islands is a small species of lizard. Birds are very numerous, and are described by all travellers as beautiful songsters. Amongst the feathered tribe may be mentioned ducks, geese, woodcocks, snipes, curlews, and wood-pigeons, as affording food to man. Some of the birds are very remarkable. One, called by the natives the *tui*, has the power of imitating the notes of all the other birds with great exactness. Another, called the *kiki*, is about the size of a young turkey, and its plumage resembles that of the Australian emu, being long, straight, and coarse. It has neither wings nor tail, but runs with great swiftness along the ground, and can only be caught by dogs. Fish are very abundant all round the coast, and are of most excellent quality. Whales also frequent the coasts of New Zealand for the purpose of calving, and are caught in large numbers. This trade alone is very considerable, and would no doubt be greatly extended were settlements more numerous in the country.

The aboriginal natives of New Zealand were formerly savage and dangerous, but are now partially improved, and harmless in disposition. From all accounts they are susceptible of much greater improvement than the natives of Australia, being ready in apprehension and tractable. They generally dwell in small villages. In their intercourse with Europeans, the New Zealanders have on all occasions manifested a desire to learn, and great aptitude in acquiring civilised customs. Regarding the amount of the native population, it can only be guessed at—probably about 90,000.

The first attempt to colonise New Zealand was made in 1825, by a company under the auspices of the Earl of Durham. Two vessels were despatched to the country by this company, and some land was acquired at Herd's Point on the Hokianga River, but the idea of settling it was soon after abandoned. Meanwhile the missionaries had acquired considerable tracts of land in different parts of the islands, and introduced many

farming improvements, along with the religious instruction which they bestowed upon the natives. A company, called the New Zealand Association, was started in 1837; and another, under the name of the New Zealand Colonisation Company, in 1838. These companies may be said to have merged in a New Zealand Company, which was established in May 1839, and which, since that period, has been actively engaged, after many obstructions both from the natives and from the home government, in establishing settlements chiefly in Cook's Straits, as Wellington, Nelson, &c. In 1840 a regular colonial government was established, after the model of the Australian settlements, with Auckland in the northern island as the capital. Various settlements have since been effected in both islands—the most recent being that of Otago, on the eastern coast of the middle island, under the auspices of the New Zealand Company and the Lay Association of the Free Church of Scotland.

In 1842 the colonial population was estimated at 17,000, but must now exceed 23,000. In the same year the value exported to Britain was £10,998, while the imports from Britain amounted to £42,753.

## POLYNESIA.

Polynesia—from two Greek words, signifying *many isles*—is the name given to the numerous groups scattered over the central parts of the Pacific Ocean, within 30 degrees on both sides of the equator. The chief clusters north of this line are the *Sandwich* in the east, and the *Ladrões* and *Carolines* in the west; and south of it, the *Marquesas* in the east, the *Society* Islands in the middle, and the *Friendly*, including the *Féjee* and *Navigators'*, in the west. The Sandwich, Society, and Marquesas Islands are of volcanic origin—steep, rugged, and lofty; the active craters of Owhyhee being 13,000, 14,000, and 16,000 feet above the sea level, and the verdant and wooded heights of Tahiti rising to an elevation of 10,000 feet. The other groups, with few exceptions, are entirely of coral formation, elevated but a few feet above the sea, and appearing as long narrow reefs, circular reefs enclosing lagoons, or barrier reefs encircling inner islets, from which they are separated by deep narrow channels.

Situated within the tropics, but with an atmosphere tempered by the surrounding ocean, and in the larger islands by the above-mentioned mountains, the climate is delightful, and the soil exceedingly fertile. Among the native productions are the bread-fruit, cocoa, bananas, pandanus, plantain, and a variety of tropical fruits; the taro, yam, batata, and other farinaceous roots. Among those successfully introduced are the orange, lemon, sugar-cane, cotton, potato, melon, cucumber, guava, &c. The only quadrupeds found on the islands when first visited by Europeans were hogs, dogs, and rats; but birds were numerous, consisting of poultry, pigeons, turtle-doves, parrots, and other tropical genera. The shores abound with seaweed; and the sea teems with a vast variety of fishes, shellfish, crustacea, turtles, seals, and cetacea. The ox and horse have been brought to some of the larger islands from Europe or from America.

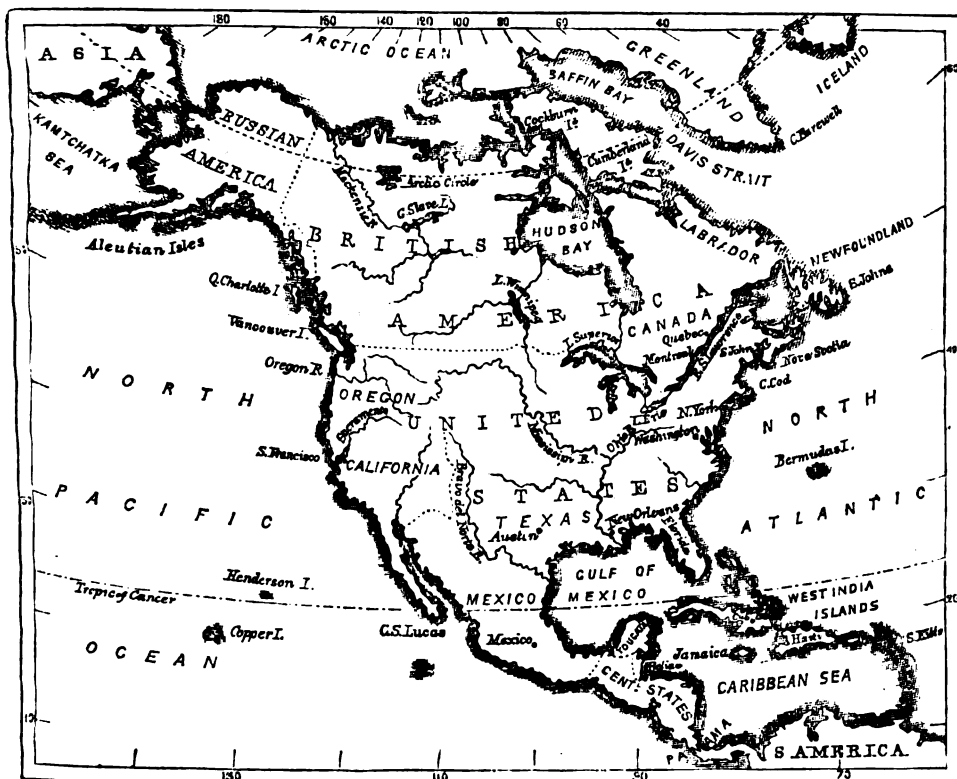

The natives seem to belong to the Malay variety of the human race, and have generally been found much more tractable than the barbarous tribes in other parts of the world. When first discovered, they were wholly idolatrous, addicted to cannibalism, infanticide, and similar vices; to the superstition of fetish and taboo; and to the fashion of tattooing. Within the last forty years a large proportion of the inhabitants of the Sandwich, Society, and Friendly Islands have embraced Christianity; and missionaries from the United States of America and Britain have taught them reading, writing, and a number of useful arts.

The only foreign powers having possessions in Polynesia are the Spaniards, who have occupied the Ladrões since the end of the seventeenth century; and the French, who, since 1843, have attempted the occupation of the Marquesas.

# NORTH AMERICA.

This is the largest, and in every respect the most important division of the western hemisphere. It is bounded on the east by the Atlantic; on the south by the Gulf of Mexico and the Pacific, save where connected to South America by the narrow Isthmus of Panama; on the west by the Pacific; and on the north generally by the Arctic Ocean. We say gene-

rally, for its northern shores are yet imperfectly known, and are at the present moment the object of farther exploration. If we adopt the opinion of Mr Simpson, who traversed the coast from Point Barrow to Point Turn-again, that the waters of Melville Sound are connected with the Gulf of Boothia, then is North America distinct from the arctic regions of Cumberland

Island, New Georgia, and Greenland, which will require to be erected into a new geographical division. Following, however, the usual course of including these regions, and leaving the 'north-west passage' as still problematical, the area of the known continent may be stated at 8,000,000 square miles—the great mass of which lies within the northern temperate zone.

### SUPERFICIAL FEATURES—GEOLOGY.

The general physical characteristics of the continent are remarkable for the magnitude of the scale upon which they are presented; the mountains, plains, lakes, and rivers, being superior to those of all other countries. They are thus summarily described in the System of Universal Geography:—1. The narrow region which separates the Gulf of Mexico and the Caribbean Sea from the Pacific, traversed throughout its whole length by mountain-ranges, which leave a narrow tract of low land lying along the sea-coasts, while in certain portions of the interior they form elevated table-lands. Here the mountains (which may be considered as the commencement of the great Rocky chain) attain a culminating point in Guatemala of 14,900, and in the Mexican volcano of Popocatepetl of 17,735 feet; while the table-land of Mexico is from 4000 to 8000 feet in

general altitude. 2. The maritime region between the Pacific Ocean on the west and the ridge of mountains which extends from Cape St Lucas in California northwards to Alaska. This ridge has a general elevation of 8000 or 10,000 feet, but rises in Mount St Elias to 12,630. 3. The elevated region which forms a sort of table-land between the maritime chain before-mentioned on the west and the Rocky Mountains on the east. In its southern portion it presents the arid salt-plains of the Californian desert; between 40° and 45° north it presents a fertile region, with a mild and humid atmosphere; but beyond the last-mentioned parallel it is barren and inhospitable. 4. The great central valley of the Missouri and Mississippi, extending from the Rocky Mountains on the west to the Alleghanies on the east, and from the Gulf of Mexico northwards to the 45th or 50th degree north lat. Between these parallels runs in a waving line the watershed which divides the basins of the St Lawrence and the Mississippi from those of the streams that flow to Hudson's Bay and the Arctic Ocean. On the east side this region is rich and well-wooded; in the middle it is bare prairie ground, but not unfertile; towards the west it is dry, sandy, and almost a desert. The Rocky Mountains, the greatest and most continuous of the

North American chains, rise from 8000 to 10,000, occasionally to 12,000, and only between lat. 52° and 53° north to 16,000 feet; while the Alleghanies reach their culminating point at 6476 feet, and sink down in their branches to 3000 and 2000 feet. 5. The eastern declivities of the Alleghany Mountains and the maritime region, extending to the shores of the Atlantic. This is a region of natural forests, and of mixed, but rather poor soil. 6. The great northern plain beyond the 50th parallel, four-fifths of which are a bleak and desolate waste, overspread with innumerable lakes, and resembling Siberia (No. 67) in the physical character of its surface and the rigour of its climate.

The geology of the continent, with the exception of the United States, parts of Mexico, Canada, and Nova Scotia, has been but imperfectly examined; but so far as observation has gone, all the usual formations or their equivalents have been detected. Granite, syenite, porphyry, gneiss, and the other primitive rocks, are found in Mexico, in the Rocky Mountains, in the Alleghanies, and on the arctic shores. Overlying these, in Mexico, are transition and other older strata; the Rocky Mountains are flanked by transition and secondary rocks, up to the new red sandstone and saliferous marls; while, flanking the Alleghanies, and taking on in succession, are all the secondary rocks, up to the equivalents of the chalk and green-sand, though no true chalk has yet been detected. Deposits of the tertiary era are abundant in the United States, though not presenting the same mineral aspect as the limestones, clays, and gypsums of the Paris Basin; and in no country in the world are there more extensive displays of post-tertiary and alluvial accumulations—attesting the recent rise of a great portion of the American continent above the waters of the ocean. No active volcano, with the exception of Mount St Elias in the Russian territory, is found north of the Mexican table-land; but evidences of recent extinction are said to be rife in the Rocky Mountains. Fossils, analogous and contemporaneous with those of the old world, have been discovered in the United States—from the curious transition trilobite, down through the coal Flora and the footsteps in the new red sandstone, to the lately-existing mastodon and megatherium. (See GEOLOGY.)

The economic minerals are numerous and valuable—namely, granite and building stones of every kind; marble in the United States; gypsum in the United States and Nova Scotia; limestone almost in every part; salt springs plentifully in the United States, California, and Mexico; coal, both anthracite and bituminous, in inexhaustible fields in the United States and Nova Scotia; petroleum, asphalt; springs of carburetted hydrogen, which serve for light; and other minor minerals. The chief metals are—gold in Mexico, California, and the Carolinas; silver in the Central States; iron in the United States, Canada, Mexico, &c.; copper in the United States, Canada, and the far north; lead abundantly in the Western States and Upper Canada; and tin and mercury in Mexico.

The islands, peninsulas, promontories, and other features which give diversity to the sea-coast, appear to be most numerous in the north—the region of least importance, and with which we are the least acquainted. Passing, therefore, the *islands* in that quarter, the principal on the east are—Newfoundland, a large low island, indifferently wooded, defaced by lakes and marshes, but celebrated for its adjacent cod-fisheries, 350 miles long, with an average breadth of 130; Anticosti, in the Gulf of St Lawrence, sterile, and all but uninhabited; Prince Edward's Island, somewhat hilly, well wooded, and in part cultivated, about 140 miles long, with an average breadth of 34; Cape Breton, a large irregularly-shaped island, with an area of 4000 square miles or thereby, wooded, abounding in excellent coal and valuable fisheries, but with an indifferent moist and foggy climate. On the west or Pacific seaboard are—the now important island of Vancouver, Queen Charlotte's and George III.'s Archipelago, and other sterile rocky islets, of which we know little beyond the position,

and that with no great degree of accuracy. The most striking *peninsulas* are—Greenland, Nova Scotia, Florida, Guatemala, or the Central States, and Yucatan on the east and south; California and Alaska on the west. The more prominent *capess* are—Farewell, the southernmost point of Greenland; Capes Chidley and Charles in Labrador; Race in Newfoundland; Sable and Canso in Nova Scotia; Cod and Hatteras in the United States; Sable, the extreme point of Florida; Catoche in Yucatan; St Lucas in California; Cape Prince of Wales, the guardian headland of Behring's Straits; and Icy Cape and Point Barrow in the Arctic Ocean. The only *isthmus* deserving of notice is that of Darien or Panama, which connects North and South America, and which at one place opposite Mandingo Bay is little more than eighteen miles. Various schemes have been recently proposed for the crossing of this narrow neck by canal, with a view to facilitate the communication between the Atlantic and Pacific. From the surveys made, there seems to be no engineering difficulty which may not be surmounted; the only question is, at whose instance, and under what conditions, ought a work of such universal utility be undertaken?

#### HYDROGRAPHY.

The chief gulfs are—Hudson's Bay on the north, a large inland sea, 800 miles long by 600 broad, interrupted by shoals and islands, frozen for the greater part of the year, and girdled by sterile desert shores; subordinate to the above are James's Bay, 250 miles long by 150 broad, and Chesterfield inlet, penetrating westward for 270 miles; Hudson's Strait, 500 miles in length, and only about 80 miles at its narrowest part; Baffin's Bay and Davis' Strait, celebrated for their whale fisheries; Bellisle Strait, separating Newfoundland from the mainland; the Bay of Fundy, between Nova Scotia and the mainland, 180 miles long, and about 33 in breadth, of dangerous navigation, in consequence of fogs and the velocity of the tide, which sometimes rises as high as 70 feet; Chesapeake Bay, a valuable inlet 180 miles in length, with a breadth varying from 25 to 7; the large land-locked Gulf of Mexico, noted for its low alluvial shores, the high temperature of its waters, and its currents (Gulf Stream), which passes with great velocity through the narrow Strait of Florida; the Caribbean Sea, bounded on the east by the West Indian Islands, through which it communicates with the Atlantic by numerous passages; on the west, the Gulf of California, penetrating inland for 700 miles, with a breadth varying from 40 to 150 miles, celebrated for its pearls; and the Strait of St Juan de Fuca, now forming a neutral boundary between the United States and British America.

The fresh-water lakes of North America are the largest, and in many respects the most valuable, in the world. The whole region between 42° and 67° north is so completely covered with them, that geographers have styled it, by way of eminence, the Region of Lakes. We can only mention a few of the more important:—1. Superior, 420 miles long by 168 broad, covering an area of 35,000 square miles; its surface is 625 feet above that of the ocean, but its depth is upwards of 1000 feet. It has, like all the others, no tidal ebb or flow, is studded by few islands, and, from the unsheltered nature of its shores, affords no great facility for shipping. It discharges its surplus waters by the river St Mary, which, after a course of 80 miles, and a descent of 32 feet, falls into—2. Lake Huron, having a length of 280 miles, and a breadth of 250; area 20,000 square miles, and medium depth 960 feet. It has several large islands, among which are the Manitoulin chain, which almost separates that portion known as Lake Iroquois or Georgia Bay from the main body of the lake. 3. Michigan, on the same level with Huron, with which it is connected by the Mackinaw Strait, little more than four miles across. This sheet is 300 miles long, and about 60 broad; area 16,000 square miles, and depth 900 feet. The shores are low and open, and consequently afford no good natural har-

## NORTH AMERICA.

bouage. 4. Lake Erie, receiving the surplus waters of Huron by the navigable rivers St Clair and Detroit—the former, after a course of 80 miles, expanding into a shallow lake, which again contracts into the latter, also about 30 miles long. Erie is 230 miles long by 40 broad; area 10,000 square miles; its level 560 feet above the sea, and depth 120 feet. The shores of this sheet are low, with a marshy or sandy beach. 5. Ontario, receiving the surplus waters of Erie by the Niagara, which has a descent of 330 feet, 165 of which are by the celebrated Falls of that name, and 51 by the rapids beneath. This lake is 200 miles long, and 40 broad; area 7200 square miles, and mean depth 500 feet. Ontario discharges its waters by the Kataragui, and the Lake of the Thousand Islands, which afterwards becomes the St Lawrence. The other principal lakes are—Athabasca, Winnipeg, Great Slave Lake, and Great Bear Lake in the Hudson's Bay Territory; and Nicaragua in the Central States.

With respect to rivers, no country is more bountifully supplied than North America; almost every part of its interior being accessible by their means. The Mississippi—reckoning from the source of the Missouri, its true head—has a course of 4300 miles, for 3900 of which it is navigable for boats. It has been calculated that the basin of this river has an area upwards of 1,300,000 square miles, and that the whole amount of boat navigation afforded by the river-system, of which it is the main trunk, is nearly 40,000 miles. Its principal affluents are the Roxo, Arkansas, La Platte, and Yellowstone on the west; and the Tennessee, Ohio, Wabash, and Illinois on the east. The St Lawrence, estimating its course from the head waters of the rivers flowing into Lake Superior, drains a territory of 600,000 square miles, and affords a partially interrupted boat navigation of 4000 miles. The other large rivers are the Mackenzie, flowing into the Arctic Ocean, navigable during the short polar summer, as proved by Dease and Simpson; the Columbia or Oregon, a rapid and obstructed stream; the Bravo or Del Norte, the watering river of Texas; and the Colorado in California. These, as well as many others of the minor rivers, exhibit in their course some of the magnificent and picturesque waterfalls, of which Niagara (165 feet) and Montmorency in Canada (250 feet), the Katerskill (175), Taoukanic (160), and Great Falls (150) in the United States, may be taken as examples.

### CLIMATE—BOTANY—ZOOLOGY.

Of climate, although there must necessarily be a great variety in such a vast extent of continent—stretching from the limits of perpetual verdure to those of perpetual ice—yet it does not agree in particulars from what might be anticipated from an acquaintance with the climatology of different places in the eastern hemisphere. It is usually stated that the temperature in any latitude in America is, upon an average, 10 degrees less than in the same parallel of the old world. The latitudes which are temperate in Europe, for example, are extremely cold in America; and at the same time no part ever suffers under that intense heat which scorches up the torrid zone of Africa and Asia. The coldness of North America is partly attributable to the extent of land uninterrupted by seas, partly to the amount of surface under the frigid zone, and partly to the general elevation of the country. Cold currents of air are constantly passing from the north over the interior, while cold currents of water are as regularly passing from the Arctic Ocean southwards along its shores. The western coast is considerably warmer, however, than the east; and altogether, it is supposed that it will be impossible to carry the arts of civilised life beyond the 60th parallel, on which may be said to be situated the capitals of Norway, Sweden, and Russia in Europe. With this general outline we must here close, referring for particulars to the respective countries hereafter described.

The vegetation of the northern regions greatly resembles that of Lapland in Europe—dwarf willows,

larches, poplars, and pines; mosses and lichens; and a scanty herbage, interspersed by a few wild flowers during summer. In the Canadas, and generally in the basin of the St Lawrence, the true forests of American pine and fir prevail, though the trees are inferior in size to those of the United States. Interspersed with these, and becoming more frequent as we proceed southward, are the white cedar, sugar-maple, basswood, hickory, several species of oak, and wild cherry. Here also flourish the Canadian lily, the ginseng, Venus's fly-trap; the cultivated grains and fruits of temperate Europe; with tobacco, hemp, and flax. In the United States—which presents three very different zones of climate—are found a greater variety of species than in almost any other region of the same dimensions. The first zone, north of lat. 44°, exhibits birch, elm, red and white pines, sugar and other maples, a variety of oaks, and the vegetation common to Canada. Between this zone and 35°, oaks, ash, hickory, plane, white cedar, sassafras, witch-hazel, cornel, yellow birch, and red maple become more frequent, as do also fine flowering climbers and aquatics. South of this middle zone, and up to 27°, most of the foregoing are found, with deciduous cypress, Carolina poplar, magnolias, swamp-hickory, lobelias, and a greater variety of climbers and aquatics. South of 27° the vegetation merges into the tropical, or that to be described under the West Indies and South America. As already stated, all the common garden fruits of Europe are reared in the north; pomegranates, melons, figs, grapes, olives, almonds, oranges, &c. in the southern zone. Maize is grown all south of Maine; tobacco as far north as lat. 40°; cotton to 37°; the sugar-cane to 32°; rice in the Carolinas, Louisiana, and Georgia; wheat all over the Union; oats and rye principally in the north; hemp, flax, and hops chiefly in the western and middle districts. (See subsequent sections.)

The Fauna of North America is in many respects peculiar, and has, besides, no analogy to several of the forms common in the old world. Of *mammalia*, we may mention the tailed monkeys of Mexico; the puma, lynx, glutton, wolf, American fox; polar, black, and grisly bears, badger, otter, racoon, opossum, beaver, skunk, ermine; prairie dog; bison, wapeti, prong-horned antelope, moose, red, Virginian, and other deer. Among *birds*—the white-headed and other eagles, various vultures, wild turkey, Canada goose, passenger-pigeon, bell-bird, mocking-bird, humming-birds, &c. Of *reptiles*—the alligator, tortoise, rattlesnake, black-snake, siren, &c. Of *fish*, &c. a vast and useful variety—as cod, sprat, mackerel, salmon; crab; oyster, and other shell-fish. Of useful *insects*, the continent possesses the bee and cochineal insect, and is infested with the mosquito. All the domestic animals of Europe have been introduced with success.

### POPULATION—COUNTRIES.

The people who inhabited the continent at the time of its discovery in 1492, belonged exclusively to the American variety of our species, but subdivisible into numerous families and tribes, differing not so much in physical aspect as in manners and customs. Without descending to minutiae, the aborigines might be classed into the *Toltecans*, or *Aztecks*, a civilised race who inhabited Mexico, and had made considerable progress in the domestic arts; the *Indian* tribes, who led a savage life, obtaining their subsistence chiefly by hunting and fishing; and the *Esquimaux*, who peopled, as they do now, the shores of the northern seas. Soon after the discovery, several European settlements were formed at various points along the eastern shores of the continent, from the Isthmus of Panama to the Gulf of St Lawrence, and these settlements have been gradually extending, either by purchase from the natives or by conquest, till now the whole of the country may be said to be under European supremacy, before which the Red Man is gradually but surely passing away. The Spaniards colonised Mexico; the French settlements extended along the St Lawrence and Mississippi; and the

## CHAMBERS'S INFORMATION FOR THE PEOPLE.

English chiefly along the eastern shores; where also settled Scotch, Dutch, Germans, and Irish. Out of all these have been formed the now dominant Anglo-American family, which holds subordinate the few remaining Indian tribes, the vast population of African negroes imported as slaves, and the half-breeds resulting from intermixture with the white and coloured races.

Politically, the original settlements have undergone many mutations: most of them have declared themselves independent, and adopted republican governments; some have changed masters; and only a few remain in unaltered connection with the mother country. The following table exhibits the existing political divisions of the continent:—

Countries.	Sq. Miles.	Population.	Chief Towns.
Russian America,	500,000	50,000	New Archangel.
British America,	2,900,000	2,000,000	Quebec.
Danish Greenland,	...	7,000	Good Hope.
United States,	2,650,000	17,095,000	Washington.
Mexico,	900,000	8,000,000	Mexico.
Central States,	186,000	2,000,000	S. Salvador.
Yucatan,	76,000	570,000	Merida.

Such are the existing divisions or governments, the physical, political, social, and industrial features of which we shall now endeavour to describe as fully as our narrow limits will allow:—

### RUSSIAN AMERICA.

This territory comprehends the north-western corner of the continent, together with the adjacent islands, forming in all an area about 500,000 square miles. It is in the immediate possession of the Russian-American Company, whose chief object is the collection of peltry for the Chinese market; but their dominion over such a vast and inhospitable region is merely nominal. The natives who live along the coasts, and barter furs and skins with the Company's agents, acknowledge in some degree the sovereignty of the empire; but those of the interior are utterly ignorant of, and uncontrolled by, any idea of extraneous authority. They are comparatively few in number, are thoroughly savage, and subsist wholly by fishing and hunting. As a race, they are rather under the middle size, are of a dark-brown complexion, and seem, especially towards the coast and on the islands, to be intermediate between the Mongolians and true Americans of the interior. The white population form a mere handful of agents and their servants—inhabiting the forts or settlements, which are few and widely separated. The chief of these is New Archangel—the capital of the country—containing a mixed population of 1000. It is situated on the west coast of Sitka Island, and contains the boards and warehouses of the Company. As a region, Russian America is sterile, dreary, and unimprovable; even the trade which it at one time possessed is rapidly on the decline, in consequence of the unsparring massacre of the animals—sea-otters, seals, sea-lions, foxes, wolves, &c.—which yielded the furs and peltry.

### BRITISH AMERICA.

British America embraces a territory nearly as large as Europe, and comprises—1. The bleak region of New Britain, inhabited by the Esquimaux and other savages, and by the forts or fur depôts of the Hudson's Bay Company; 2. Upper and Lower Canada, united into one colonial province in 1841—the former settled chiefly by emigrants from Britain and the United States, and the latter originally settled by the French, but conquered in 1769; 3. New Brunswick, noted for its timber and fisheries, ceded by the French at the peace of 1763; 4. Nova Scotia, first settled by the French, and along with New Brunswick called Acadia, but subsequently fell under the English, and after several times changing masters, was finally acquired by Britain in 1763—possesses coal, gypsum, wood, and abundant fisheries; 5. Prince Edward's Island, also taken from the French in 1768, and an-

nexed to Nova Scotia, but since 1768 has formed a separate colony; 6. Newfoundland, noted for its productive cod-fisheries, discovered by the English in 1497, but not successfully established as a colony till 1623; and, 7. To these may be added the settlement of Belize on the Bay of Honduras, transferred from Spain to England by treaty in 1670—valuable for its mahogany and logwood. Of these territories and colonies, as more especially interesting to British readers, we may offer a few details:—

### New Britain.

or, as it is commonly termed, the Hudson's Bay Territory, comprehends the whole lands in North America granted by the British government to the Hudson's Bay Company. The boundaries of these lands were never very satisfactorily defined. Originally limited to the districts drained by the rivers falling into Hudson's Bay, they have, since the union of the Hudson's Bay and North-West Companies in 1821, been regarded as comprehending the whole of British America, with the exception of the settled provinces or crown colonies. The territory, as might be expected from its vast extent, presents considerable variety in physical character, though on the whole cold, dreary, and uninviting. In the north, vegetation is scanty and stunted; as we travel southwards, the pine forests begin to appear, till in the southern regions on both sides they become dense, with open spaces of lake, morass, and prairie ground. With the exception of Red River district, near Lake Winnepeg, which was sold by the Company to Lord Selkirk, and is assuming the form of a European settlement, the whole territory may be regarded as a vast hunting-ground, occupied by buffaloes, musk-oxen, deer, bears, wolves, foxes, beavers, lemmings, ermines, and other fur-bearing animals—the skins of which constitute the principal value of the territory. No doubt copper, iron, lead, plumbago, coal, and salt have been discovered in several places; but these, without the facility of being mined and transported, remain unemployed and worthless. The population, amounting to about 140,000, consists chiefly of various Indian tribes, who roam over the interior; of Esquimaux, inhabiting the northern and eastern coasts; and of the officers and servants of the Company (with a sprinkling of half-castes), who inhabit the forts or factories.

With respect to the Hudson's Bay Company, which was chartered in 1670, and possesses the monopoly of the fur trade in these regions, 'the supreme direction (we quote Waterston's 'Cyclopædia of Commerce') is vested in a board consisting of a governor, deputy-governor, and seven directors, who hold their sittings in London. A resident governor appointed by them has the superintendence of all the settlements, and is assisted by local councils, composed of the principal officers in each district, who meet him at central points during his annual tours of inspection. The acting officers consist of chief factors, each of whom has charge of several posts, of principal and secondary traders, and of clerks. The higher offices are filled up, according to merit, from the inferior ones; so that it is perfectly open for a clerk to rise to the rank of chief factor. The Company have at present in their employ about 1000 Europeans, and their descendants by Indian wives. They have four or five principal stations: York Fort, the most important, commands all the vast region extending west and north of Hudson's Bay; Moose Fort, at the south extremity of Hudson's Bay, presides over all the country between that gulf and the Canadian lakes; Ungava Bay, at the exterior entrance of Hudson's Bay, contains a small station for collecting the produce of the adjacent coasts of Salvador, consisting chiefly of oil from the seal and porpoise; Montreal is the centre of the transactions carried on in the Canadas. The Company has also several stations west of the Rocky Mountains, the chief of which was Fort Vancouver, on the Columbia River; but since the adjustment of the Oregon boundaries with the United States, the chief factory has been removed to Vancouver;

## NORTH AMERICA.

Island, which, during the present year (1849), has been given by the crown to the Company as a field for colonisation. Possessing wood, coal, iron, and, it is said, other metals; having a favourable climate; and affording facilities for shipping, Vancouver Island is likely to assume considerable importance; and this all the more rapidly from its being the nearest British territory to the now El Dorado of California. The annual value of the imports from Britain to the Hudson's Bay Territory is estimated at £55,000; while that of the peltry and other articles exported varies, according to circumstances, from £40,000 to £70,000.

### Canada.

Canada is bounded on the east by the Gulf of St Lawrence, on the north and west by the territories of the Hudson's Bay Company, and on the south by the United States and the British province of New Brunswick. Until a recent period, Canada was divided into two provinces, the Upper and Lower, each of which had its own local government; but by an act of the imperial parliament in 1841, the two provinces are united under one general Legislative Council and House of Assembly, two bodies respectively resembling the Houses of Peers and Commons in the mother country, and whose measures require the consent of the governor, as the acts of the home parliament require that of the sovereign. The affairs of this, as of all other colonies, are subject to an ultimate control, vested immediately in a colonial minister, but finally in the British legislature. In Lower or Eastern Canada, the greater part of the population is of French descent (this having originally been a French colony): the laws resemble those of France, and the French language is generally spoken. Upper or Western Canada lies to the west and south-west of the lower province. Its inhabitants are of British descent, and a very large proportion of them are from Scotland, both Lowlands and Highlands. The English law and church are here established; but there is the most perfect liberty of conscience, and as great a security of life and property as in Britain. The aggregate area of the provinces has been estimated at 355,000 square miles, and the population at 1,225,000.

Western Canada, which is the finer and more eligible section, is divided into districts, counties, ridings, townships, special tracts, and allotments, together with blocks of land reserved for the clergy and the crown, and lands appropriated to the Indians. A district contains one, two, or three counties, and each county contains from four to thirty townships. The line of division betwixt Western and Eastern Canada is in one part the Ottawa or Grand River. Nearly all the other lines of division in the provinces are straight, without regard to physical distinction, such as hills and rivers; and this peculiarity is common over the whole of North America. The entire area of Upper Canada has been estimated at 64,000,000 acres. Of this extent of territory, the portion laid out in townships, and open for settlement, amounts to nearly 17,000,000 acres, the size of each township averaging 61,600 acres. Deducting the quantities granted to different classes of settlers, and otherwise disposed of by the crown, there yet remains within the townships, at the disposal of government, about 3,000,000 acres. This tract of country, chiefly bordering the north shore of the river St Lawrence, and of the lakes Ontario, Erie, and St Clair, and of the rivers or straits communicating between these lakes up to Lake Huron, a distance in all little short of 700 miles, and stretching northward from the water to a depth varying from 50 to 80 miles, is composed of a soil which, for productive richness, variety, and applicability to the highest purposes of agriculture, may challenge competition with the choicest tracts of land in the new world.

Western Canada is chiefly a flat country, and is for the greater part covered with timber, but possesses a number of chains or ridges of high lands, running in different directions, and separating the sources and channels of innumerable rivers and brooks. The grand

feature of the country is its water-courses. By looking at the map, it will be perceived that there is a series of large lakes, communicating with each other; these are unequalled by any inland sheets of water in the world, and are entitled to the appellation of fresh-water seas. The series, so far as Canada is concerned (see page 290), consists of Lakes Superior, Huron, Erie, and Ontario. The waters of Lake Erie, on issuing from its lower extremity, form a river of nearly half a mile broad, which in its course is precipitated over a precipice to a depth of 165 feet, thus making the famed cataract or Falls of Niagara. The river is, at the distance of a few miles below, received by Lake Ontario, whence issues the river St Lawrence, one of the largest streams in the world, and which, after a course of 2000 miles, falls into the Atlantic. This majestic river is 90 miles wide at its mouth, and is navigable for ships of the line for 400 miles from the ocean. In its upper parts, its navigation is impeded by *rapids*, or the rushing of the stream down an inclined plane; but some of these impediments are obviated by means of canals recently cut; wherefore there is now a continued water communication for vessels from the Atlantic into the interior or innermost lakes. The Welland Canal, a magnificent undertaking, connects Lakes Erie and Ontario, and affords a passage for vessels of large size. Lake Erie is also connected by a canal with the Hudson, a river of the United States, which also falls into the Atlantic. The Ottawa, or Grand River, is next to the St Lawrence in point of size, and is tributary to it. It falls into the north side of the St Lawrence at Montreal. The Welland, or Chippewa, is also a remarkably fine river, wholly unobstructed by falls. The St Lawrence has a tendency northward in its course, and, therefore, the farther we ascend its waters the milder does the climate of the country become.

The *climate* of Canada presents very opposite extremes of heat and cold, and the transition from the one to the other is much more sudden than in Great Britain. Notwithstanding this, however, it is healthy; all accounts which we have seen, both those of travellers and the letters of private individuals, agreeing in this respect. The spring in Canada generally commences about the end of April, and the fields are well covered with vegetation by the beginning of May. The thermometer ranges during summer from about 80° to 84°; in some instances it has reached 162°; but such extreme heat is very rarely felt. Spring, summer, and autumn extend from the end of April to October. Winter commences in November, when thick fogs and snow-storms are frequent. By the middle of December the ground is generally covered with snow, and the frost, especially in Lower Canada, becomes sometimes very intense. The depth of the snow in Upper Canada varies according to seasons, from a few inches to several feet; the average depth, taking one season with another, has been estimated to be between eighteen inches and two feet. The winter in the Upper or western part of the province is much milder than in the Lower or eastern part, and new settlers generally are pleasantly disappointed in not experiencing the rigours which, from exaggerated rumours at home, they had expected to find. January has generally a week or more of open, and sometimes mild weather; and it not unfrequently happens that it is only in February that the weather may be said to be very severe and the frost intense.

In Lower Canada, where winter is most severe, the thermometer ranges from 25° above to 25° below zero. The sky of a Canadian winter is generally almost cloudless, the air bracing, and, from the absence of wind, in spite of the low temperature, the cold is not felt to be disagreeable. From Quebec to Montreal and upwards, the St Lawrence and other rivers, and also the lakes, cease to be navigable; but the firm icy surface serves as a road for the sleighs and carriages; and although the entire face of nature is now changed—the varied and pleasing tints of autumn in the forest, and the busy and enlivening signs of commerce upon the lakes and rivers, having given place to one.

dead and drear-like scene, seemingly destitute of variety—yet the snows and frosts of Canada are hailed as ushering in a season which brings with it no small amount of social enjoyment. Winter in Canada is indeed the season of joy and pleasure: all classes and ranks indulge in a general carnival, as some amends for the more enervating toil undergone during the summer months. The double-seated sleigh, with its mettled pair of horses, or single-horse *cutter* of the Upper Canadian, or the carriage of the humble *habitan*, or proud *seigneur* of Lower Canada, is got ready all over the country. Riding abroad on business or pleasure commences; visiting is in active play between friends, and relatives; regular city and town balls, and irregular pic-nic country parties, are quite the rage.

While the external weather is guarded against by warm clothing when out of doors, the habitations of the Canadians are kept comfortably warm, the apartments being heated with stoves, which keep the temperature at a higher and more uniform rate than can be effected by English fireplaces.

The various writers on Canada each recommend particular districts for the settlement of the emigrant; but it is hardly to be expected that persons in this country can make a perfectly judicious choice, a personal inspection of the lands, or at least information near the spot, being in almost every case requisite. The most elaborate details are given by Bouchette, in his large work on British America, regarding the different parts of the province; and as what he mentions may be of use in furnishing emigrants with an idea of the nature of the lands, we take the liberty of transcribing a few of his observations:—

'The *Eastern Section* includes Ottawa, Johnstown, Midland, and Bathurst districts. Situated between two broad and navigable rivers, the Ottawa and the St Lawrence, and centrally traversed in a diagonal course by an extensive and splendid sloop canal, connecting the navigation with the waters of Ontario, this section of country evidently enjoys important geographical and local advantages. Its surface presents, almost unexceptionably, a table-level of moderate elevation, with a very gentle and scarcely perceptible depression, as it approaches the margin of the magnificent streams by which it is bounded to the northward and south-east. The soil, though sometimes too moist and marshy, is extremely rich and fertile, and chiefly consists of a brown clay and yellow loam. This section is intersected by numerous rivers, remarkable for the multitude of their branches and minor ramifications. There are also a number of good public roads, both along the St Lawrence and Ottawa, and into the interior. Great industry and attention to improvement are displayed upon most of the lands throughout this tract. The town of Kingston, the largest and most populous of the upper province, is very advantageously seated on the north side of the St Lawrence, or rather at the eastern extremity of Lake Ontario. The thriving village of Perth is situated in the township of Drummond, on a branch of the Rideau, and occupies a central position between the Grand River and the St Lawrence, communicating by tolerably good roads with Kingston to the south and Bytown to the northward, at the opposite extremities of the Rideau Canal. The first establishment, fostered by government, was made in 1815, by British emigrants, chiefly from Scotland, many of whom are now at the head of excellent farms, possess comfortable habitations, and reap the fruits of their perseverance and industry. Ascending along the shores of Lake Chaudières, the objects of note first presenting themselves are the rising colonies in front of the townships of March and Tarbolton; they are chiefly composed of families possessed in general of adequate means to avail themselves of the advantages that are incident to a newly-opened country.

The *Central Section* of the province embraces the districts of Home and Newcastle, which occupy a grant of about 120 miles upon Lake Ontario, extending from the head of the Bay of Quinté westward to the line

between Toronto and Trafalgar. Although less populous than the tract of country composing the first part of the division which we have adopted, this portion of the province does not yield to it in fertility, and is equally well watered by numerous lakes, broad and beautiful rivers, and innumerable streams and brooks. The rivers in general abound with excellent fish, and especially salmon, great quantities of which are annually speared in the river Credit, for the supply of the western country. In front of Newcastle district, on the borders of Lake Ontario, the soil consists of a rich black earth; but in the district of Home, the shores of the lake are of an inferior quality. The lands upon Yonge Street [roads are frequently called streets in Canada], which connects Toronto with Lake Simcoe, are exceedingly fertile, but so destitute of stones (for building and other purposes) as to create some inconvenience to the settlers. A sandy plain, of some extent, exists some distance north of Ontario, towards Rice Lake; but saving this, and probably one or two more comparatively insignificant exceptions, the soil of this tract of country is extremely fertile, well adapted for agriculture, and yields luxuriant crops of wheat, rye, maize or Indian corn, peas, barley, oats, buckwheat, &c. The fronts of all the townships from Kingston to Toronto are, with few exceptions, well settled; roads lead through them, from which, in many places, others branch off to the interior. At intervals, rather distant indeed from each other, there are a few small villages. On the lands that are occupied, great progress has been made in agriculture: the houses, generally speaking, are strong and well-built: and the inhabitants appear to be possessed of all the necessaries, as well as most of the comforts, that a life of industry usually bestows.' In this division is the town of Toronto, which occupies a good situation on a fine bay of Lake Ontario; population in 1840, 12,000.

The *Western Section* comprises Gore, Niagara, London, and Western Districts. The surface is uniformly level, or but slightly undulating, if we except a very few solitary eminences, and those parts of the districts of Gore and Niagara traversed by the ridge of elevated land. The variety of soils, and the diversity of their combinations, observable in these four districts, are by no means so great as might be expected in so extended a region. The whole tract is alluvial in its formation, and chiefly consists of a stratum of black, and sometimes yellow loam, above which is deposited, when in a state of nature, a rich and deep vegetable mould, the substratum beneath the bed of loam being generally a tenacious gray or blue clay, which in some parts appears at the surface, and, intermixed with sand, constitutes the super-soil. There are numerous and extensive quarries of limestone to be found in these districts, that supply the farmers with excellent materials for building. Freestone is also found, but in small quantities, and generally along the shores of the lakes. The Thames River, in this section, rises far in the interior; and after pursuing a serpentine course of about 150 miles, in a direction nearly south-west, discharges itself into Lake St Clair.

The *chief towns* in Canada are Quebec, Montreal, Three Rivers, Prescott, Kingston, and Toronto, formerly called York. The city of Quebec is the capital of Lower Canada, and stands on the extremity of a precipitous cape, on the north bank of the St Lawrence, opposite the island of Orleans. Population in 1840 about 26,000. The appearance of the town, on coming into view, is particularly striking. The city is divided into an upper and lower town; the former being of ancient date, and adopted as the seat of commerce, and the latter being the residence of the higher and more affluent classes. There are a number of fine public edifices; among the rest, the Castle of St Louis, a prominent object on the summit of the rock; the Roman Catholic and Protestant Cathedrals, the barracks, hospitals, the Quebec Bank, and a handsome monument to Wolfe and Montcalm. The institutions are in many instances of French character, and

## NORTH AMERICA.

the language of the inhabitants is French and English. As a port, Quebec has great capabilities—the basin being sufficient to contain 100 sail of the line. The amount of shipping annually entered is little short of 400,000 tons. Montreal is a city of an entirely different appearance. It is agreeably situated on a beautiful island of the same name in the St Lawrence, which measures 82 miles long by 10½ broad, and lies at the confluence of the Ottawa River and the St Lawrence. The island of Montreal is nearly level, and is scarcely excelled in fertility. The city stands on the south side of the island, and is reckoned the first in the province, in respect of situation, local advantages, and mildness of climate. The houses are well built, and the streets commodious. There are also some handsome public buildings. The literary and scholastic institutions in Montreal are numerous, and are of great benefit to the province. There are no wharfs, and the ships and steamboats sail close to the bank of the river, where there is water for vessels of 600 tons. The annual tonnage entered at the port is about 24,000; the population of the city in 1840 was 35,000.

The principal branches of industry in Canada are—agriculture, the main product of which is wheat, amounting to upwards of 11,000,000 bushels per annum; the felling and export of timber, yielding about £705,000 yearly; the preparation of pot and pearl ashes, in clearing the land of timber, there being about 36,000 barrels annually exported; and the subordinate branches of fisheries, oil, and fur trade. There are some small manufactories of different articles at Montreal and Quebec; flannel, coarse cloth, and linen are now made to some extent in various districts; iron-founding is conducted on a considerable scale in Three Rivers, Quebec, and Montreal; and soap, candles, and the like, in several of the larger towns. The chief articles of export are timber, ashes, wheat, and other raw produce; the imports are coal, metals, cordage, East India produce, and various kinds of British manufactures from Europe; sugar, molasses, rum, and hardwoods from the West Indies; and beef, pork, biscuit, rice, and tobacco from the United States. The total value of the imports average about £2,000,000, and that of the exports £1,080,000.

### Nova Scotia.

Nova Scotia is a peninsula connected with the mainland by a narrow isthmus. It measures about 300 miles in length, but is of unequal breadth; altogether, it contains 15,617 square miles, or nearly 10,000,000 acres, with a population of about 166,000. There are numerous lakes, but the greater number occur near the southern and south-western coasts, covering about one-tenth of the entire superficies. There is no part of the land thirty miles distant from navigable water, and in all parts there are fine streams and rivers. The southern margin of Nova Scotia is broken and rugged, with very prominent features, deep inlets, and craggy islands. The features of the northern coast are soft, and free from rocks. It is bounded on the north by part of the Gulf of St Lawrence, which separates it from Prince Edward's Island; on the north-east by the Gut of Canso, which separates it from the island of Cape Breton; on the west by the Bay of Fundy, which separates it from New Brunswick; and on the south and south-east by the Atlantic Ocean.

The soil of a country of such extent and such varied features as Nova Scotia must necessarily be various. If an imaginary line be drawn, dividing the province in the exact centre, from east to west, the north-western half will be found to contain by far the greatest portion of good land. On the side towards the Bay of Fundy, the soil is very rich, and free from stones, and contains many thousand acres of diked marsh land. This is alluvial land, and is made by the deposit of the tides—a sediment composed of the finer particles of soil, brought away by the rivers and torrents in their course to the Bay of Fundy, of putrescent matter, salt, &c. This land, called marsh, after it has attained a suitable

height, is diked, and the waters of the sea excluded. Nothing can exceed its fertility. In many places, particularly about Windsor and Truro, it yields three tons of hay per acre, and has continued to do so without manure for fifty years past. There is a difference in its quality. Where the water which overflows it is not much enriched by a long course through the country, it is thin, and of an inferior quality. The quantity of land enclosed in this manner is very great. At the head of the Bay of Fundy, there are 70,000 acres in one connected body. There is one marsh in Cumberland containing nearly as much land as Romney Marsh in Kent, and of a quality vastly superior. This land is found in great quantities in Cumberland, Mascan, Napan, Londonderry, Truro, Onslow, Shubenacadie, Noel, Kennetcook, Newport, Windsor, Falmouth, Horton, Cornwallis, Granville, Annapolis, &c. The next best quality of land is called by a term peculiar to America, *intervale*, an alluvial soil made by the overflowing of large fresh-water brooks and rivers in the spring and autumn. The quantity of *intervale* is incalculable. It is to be met with in every part of the province, and is frequently found covered with a long natural grass, several feet in length, and is sometimes called 'wild meadow.' The quality varies according to the size of the brook or river by which it is made, but in general it is very fertile and rich. The upland varies so much in character that it is difficult to give a general description of it.

The mineral products of this part of America are valuable; but none is so much worthy of consideration as coal, which is worked at Pictou, at Sidney in Cape Breton, and also in Cumberland county; and there can be no doubt that the possession of this mineral will constitute one of the chief advantages of these provinces over every other. In 1847, about 120,000 tons were shipped from Pictou alone. Limestone, freestone, and slate abound, of the best qualities, and there is plenty of fine clay for bricks. Iron ore has also been discovered in several places; gypsum occurs in enormous beds, and forms a valuable article of export to the United States; and 'Nova Scotia blue grits,' or grindstones, are celebrated all over America.

The climate of Nova Scotia, like that of the adjoining districts, is salubrious and pleasant, but is in a peculiar degree exposed to the extreme of summer heat and winter cold. The ground is generally covered with snow from the 25th of December till the 6th of March, in which respect it nearly resembles Upper Canada; and during this period the farmers draw upon sledges their wood and poles from the forest, and carry their produce to market. It is difficult to say when spring commences, as it is rather late and irregular in its approaches. When vegetation does begin, it is very rapid, and two or three days make a perceptible change in the amount of the foliage. The summer may be said to be short and powerful, and during the time it lasts it exerts a much greater influence on vegetation than is observable in Britain. During this period, the inhabitants go very lightly dressed. Altogether, the climate of Nova Scotia is as good as that of Scotland, if not superior; nor are there any of those local or epidemical disorders with which other countries are frequently afflicted. Although the winters are intensely cold, they are not so disagreeable as the raw changeable winters of this country, nor nearly so fatal to human life. Besides, if the settlers work during three-quarters of a year, they have ample provision for the remaining quarter, and are enabled to look forward to winter as their season of holiday enjoyment and relaxation.

Few parts of the world are so well watered as Nova Scotia. The rivers, brooks, springs, and streams of different kinds, are very numerous. Some of the lakes are extremely beautiful, containing in general one or more small islands, which are covered with a luxuriant growth of wood, and vary in every imaginable shape. The land in the neighbourhood of them is often undulated in the most romantic manner. These lakes will in time be of great service to the province; in several

instances they nearly intersect the peninsula, offering scope for inland navigation.

The fruits produced in the country are numerous. Besides a great variety of wild fruits, gooseberries, strawberries, cherries, and raspberries, there are pears of various kinds, all the varieties of English plums, apples of a very superior quality, and some finer fruits. The other vegetable products are cucumbers, potatoes, artichokes, cauliflowers, cabbages, beans, and peas. Hops are an invariable and sure crop, and may be raised in great abundance. Pumpkins and Indian corn are cultivated to a great extent. Carrots, onions, parsnips, beet, celery, and most other kitchen herbs, are produced with ease. The grains cultivated are summer and winter wheat, rye, buckwheat, barley, and oats. The natural forests are elm, cherry, white, black, yellow, and gray birch, red oak, beech, white and yellow pine, white, red, and black spruce, maples, &c.

The province has no animals of a dangerous nature. There are the elk or moose, the reindeer, lynx, otter, racoon, fox, marten, beaver, porcupine, squirrel, &c. Among the feathered tribe there are a number of birds of the same kind as in Britain, including those called game in this country, all of which may be shot and used as food without any restriction. The only troublesome insects are the mosquitoes and black flies during hot weather. The rivers abound with the finest fish, among which are salmon and trout; and the shores yield large supplies of white and shell-fish.

Nova Scotia is divided into seventeen counties, three of which are in Cape Breton. The chief towns are Halifax, Yarmouth, Pictou, Lunenburg, Liverpool, Bridgeton, Windsor, &c. in Nova Scotia Proper; and Sydney, North Sydney, and Arichat in Cape Breton. The capital, Halifax, is pleasantly situated on the slope of a rising ground, facing a fine spacious bay or natural harbour in front, on the eastern or more accessible side of the peninsula. It contains about 25,000 inhabitants, and is a central point for the foreign commerce and fishing trade of the colony. Although possessing considerable wealth and trade, and the seat of an intelligent population, it is behind English towns of the same size and inferior capabilities. Here, as elsewhere in the colonies, a dependence on the arrangements of the home government deadens public spirit, and retards that natural tendency to advance which is observable in the towns of the United States.

Cape Breton is a romantic and mountainous island, lying close to Nova Scotia on the east, and forming three of its districts or counties. The island measures upwards of 100 miles in length, by about 60 in breadth, including the numerous bays which indent the land. The natural productions of this island resemble those of Nova Scotia, though wheat is less generally grown, and oats and potatoes are raised to a considerable extent. There are large tracts of good land in the lower parts, and the expense of clearing it of timber is estimated at £3 an acre. The mineral resources of the island are valuable.

The most important branches of industry in Nova Scotia are the timber trade, mining, cod-fishery, ship-building, and agriculture. The annual exports amount to about £550,000; the imports to £800,000. The province possesses upwards of 120,000 tons of shipping; and upwards of 350,000 tons are annually entered at the various ports.

#### New Brunswick.

The province of New Brunswick, lying on the mainland of North America, contiguous to the United States and Lower Canada, consists of an extensive tract, comprising nearly 28,000 square miles, the greater part of which is still covered with dense forests. The land, however, is generally fertile, and excellently adapted for the settlement of emigrants. Besides being recommended by the fertility of its soil, it possesses innumerable rivers and streams in all directions, suitable for purposes of trade or manufacture. The climate is salubrious; the natural products numerous and valuable;

and wild animals are plentiful; and the rivers and lakes abound in fish; while along the coasts cod, haddocks, salmon, and other fish, are yielded in plenty to the enterprising fisherman. The resources of the province are thus inexhaustible, and, according to Macgregor, suitable to the maintenance of at least 3,000,000 of inhabitants. As yet, New Brunswick has a population only of 206,000, and the principal settlements are along the river St John and its lakes. On the northern side of the entrance to this large river from the Bay of Fundy stands the town of St John, the largest in the province, and the seat of an extensive trade. Frederickton, which claims to be the metropolis of the colony, is situated ninety miles above St John's on the same river; population between 3000 and 4000.

The province of New Brunswick presents an extensive line of coast to the Gulf of St Lawrence on the east, while on the north it has part of Lower Canada, which separates it from the river St Lawrence upwards. Its latent capabilities for carrying on trade with the interior are thus very considerable. Miramichi is the chief river after the St John. It falls into the Gulf of St Lawrence, and is navigable for large vessels for about forty miles. Along its banks, here and there, are seen the huts and houses of settlers, who have not made great advances in cultivation. The cutting and export of timber form the main trade of the district. About twenty miles up, on the south bank, is seen the village of Chatham, where many of the ships load, and where several of the merchants are settled, who have erected stores and wharfs. Four miles farther up stands the village of Newcastle. The total value of the exports from the province is estimated at £400,000; and that of the imports at £600,000.

#### Prince Edward's Island.

This rich and productive island is situated in the Gulf of St Lawrence, betwixt Cape Breton on the east, and New Brunswick on the west, and is separated from Nova Scotia on the south, by a strait of about 9 miles in breadth. It measures 140 miles in length, and is 34 at its greatest breadth. The general appearance of this island from the sea is level, but on landing, the scenery is varied with gentle undulations. It abounds with streams and lakes, and in many places it is indented with bays, no part being more than eight miles from the sea. The soil is in general fertile, yielding good crops of wheat and other grains; and parsnips, turnips, carrots, potatoes, and almost all the common culinary vegetables, succeed well. This island has been recommended to such emigrants as possess a knowledge of agriculture with that of the curing of fish. The climate of Prince Edward's Island is in some respects similar to that of the neighbouring countries. The winter is said to be shorter than in Lower Canada, and the atmosphere is noted for being free of fogs. Agricultural operations commence about the beginning of May, and the harvest is generally over by the end of October. The chief disadvantage this colony labours under, and which is equally applicable to the others near it, is the great length of the winter, which obliges the farmer to lay up a very large stock of hay for supporting his live-stock. The sudden manner, also, in which spring comes on abridges the period for sowing and planting, thus leaving the agriculturist comparatively idle at one season, and obliging him to work severely at another.

The inhabitants are chiefly from Scotland and Ireland, with a few Dutch and Germans. Mr Macgregor characterises them as hospitable, kind, obliging, and as, generally speaking, a moral people. The island is governed by a lieutenant-governor, council, and House of Assembly consisting of eighteen members, who are elected by the people. Charlotte Town, the capital, is situated on the north bank of the river Hillsborough, on the east side of the island. The town stands on ground which rises in gentle heights from the banks of the river, and its harbour is considered one of the best in the Gulf of St Lawrence. A small group of islands

## NORTH AMERICA.

called the Magdalens have been recently annexed to Prince Edward's Island, chiefly as fishing establishments. The total area of the colony is set down at 2134 square miles, with a population of 47,000. The annual imports exceed £61,000; the exports, £47,000; the outward shipping, 30,000 tons; the inward, 24,000 tons. The revenue at present amounts to about £12,000, and the expenditure to £8000.

### Newfoundland.

This colony, to which we have already adverted as deriving its sole importance from its productive cod-fisheries, consists of the large island of Newfoundland, the island of Anticosti, and of Labrador on the mainland. The entire area of the province is estimated at 57,000 square miles, and the population (settlers and Esquimaux) at 96,000; but these numbers must be taken merely as approximations. The islands are described as hilly, rocky, and barren, with rugged and indented shores, sparingly covered with timber of indifferent growth, and subjected to a cold and humid climate. The consequence is, that the agricultural operations of the settlers are limited to the precarious production of small quantities of potatoes, oats, and hay: their main supplies being imported from other countries. Fishing is the great object of industry, and the exports consist almost solely of dried and pickled cod, seal, cod and whale oil, seal-skins, herrings, sprats, and salmon—amounting yearly to £800,000 or £850,000. In 1842, Britain exported to the colony of Newfoundland produce and manufactures to the amount of £277,000, and imported from thence produce to the value of £247,000.

The administration of the colony is vested in a governor, with executive and legislative councils, and a House of Assembly, consisting of fifteen members. The principal town and port is St John, with a population of from 10,000 to 15,000. The settlements are confined to the shores, on account of the fisheries, which are conducted chiefly along the coasts of the island, off the shores of Labrador, and upon the well-known submarine banks which stretch towards the south-east into the depths of the Atlantic.

### Belize or Honduras.

This settlement is far removed from the great mass of British America above described, being situated along the east coast of the Central States on the Bay of Honduras. Its area is ill defined, but has been estimated at 62,740 square miles, with a population of 9,000, of whom only 300 or 400 are whites. Its products and peculiarities are thus briefly described in the 'System of Universal Geography':—'The coast is flat, and is bordered with reefs and low green islands called *keys*, which are divided by dangerous and intricate channels. From the coast the ground rises gradually into an elevated region covered with forests and marshes, and interspersed with rivers and lagoons. The climate is moist, but is said to be less unhealthy than that of the West Indies, especially during the wet season. (See No. 70.) The shores and river banks are covered with a deep and rich alluvial soil, capable of yielding most European as well as tropical products. The forests abound with some of the finest timber-trees, including mahogany and logwood, which are the staple productions of the settlement, and the cutting of which is the principal employment of the settlers. The profits, however, of this trade are exceedingly precarious. Cassava, yams, arrowroot, and maize, are grown, but only for home consumption; cocoa and an inferior kind of indigo are indigenous. Oranges and many other fine fruits are very abundant. European cattle and other domestic animals thrive greatly. The jaguar, tapir, armadillo, racoon, gray fox, deer of various kinds, and a vast number of monkeys, abound in the settlement; birds and fish are in great variety; and shell-fish are particularly plentiful. Many turtles are also taken on the coasts and sent even to London.'

Honduras is governed by a superintendent nomi-

nated by the crown, and by seven magistrates elected annually by the people. Belize is the only town and port, and is built upon both sides of the river of that name. The houses, constructed of wood, are raised eight or ten feet above the ground on pillars of mahogany; population between 4000 and 5000, of whom only a few hundreds are whites. The port of Belize offers considerable facilities for shipping, and has of late years become the depôt of British merchandise destined for the Central States. In 1842, the exports from Honduras to Britain exceeded £864,000; the imports from Britain about £120,000.

Little requires to be said respecting the trade of Canada, or of British America generally. To Halifax, Quebec, Montreal, St John, and other ports, shipments of English manufactured goods and foreign produce are regularly made, chiefly in spring and autumn, and the produce returned is wood, fish, oil, potashes, salted beef and pork, some butter and cheese, and of late a not inconsiderable supply of wheat and flour. The total of our exports to British America was, in 1846, about £3,308,059, while the military and civil expenditure incurred by the mother country is generally little short of £500,000, thus showing that, as regards commerce, Britain loses a considerable sum yearly by maintaining these colonies. British America is highly favoured by being permitted to send its produce at comparatively low duties to the home country; but from lack of capital or enterprise, this does not appear to have so important an effect as might be expected on the prosperity of the colonies. The comparatively independent, easy, and comfortable circumstances, with light taxes, experienced by colonial farmers, may perhaps account most naturally for the absence of ambition or enterprise among a scantily-educated and plain-living people.

### GREENLAND.

This extensive insular or peninsular region—for its northern frontier is still undefined—occupies the north-eastern corner of the North American continent, and, together with the adjacent island of Iceland, is subject to Denmark. Surrounded, so far as is known, by the ocean, it lies compactly together, presenting comparatively few of those inlets and sounds usually so characteristic of northern regions. It is described as 'a barren mountainous country, nearly the whole surface of which is covered with perpetual ice and snow; which in many parts form glaciers to the very shores, where they appear as icy cliffs several hundred feet high.' The eastern coast generally rises in high masses of rock and ice close to the shore, and is beset during the whole year with enormous masses of ice which render vegetation almost impossible, and the fishing exceedingly precarious. Accordingly, only a few Esquimaux inhabit this quarter. The western shores (in Baffin's Bay) are also high and rugged, but being more indented by inlets, and less rigorous in climate, they are not so much encumbered with ice, and are more sheltered along the low grounds, which present a scanty vegetation of lichens, mosses, dwarf birch, and willow. The land animals are—the reindeer, the polar bear, the dog, hares, and foxes; the marine—whales, walrus, seals, cod and other fish, and sea-fowl in abundance. This region is accordingly better peopled, and it is here that the Danes have established a few petty settlements, chiefly commercial and missionary. The native population is estimated at 6000 or 7000, and the European at 150 or 160.

The chief employments are fishing, seal-hunting, and fowling; the settlers attempt the rearing of potatoes and a few culinary vegetables, and also the feeding of a few sheep, but, it must be confessed, with very indifferent success. The main dependence of the country is on its marine resources; hence the Danes export from their different settlements train-oil, fish, whalebone, seal-skins, fur, and eider-downs—the trade giving employment to five or six vessels. The imports in return are principally coffee, tobacco, snuff, and brandy. The country also reaps some advantage from

CHAMBERS'S INFORMATION FOR THE PEOPLE.

the numerous whaling vessels which frequent Baffin's Bay and Davis' Straits. Nevertheless it is a poor, dreary, and inhospitable, though not unhealthy region, offering no inducements whatever to the civilised settler.

UNITED STATES.

These States occupy the middle division of the continent, and are bounded on the north by British America; east by British America and the Atlantic; south by the Gulf and republic of Mexico; and west by the Pacific; having a frontier line of about 10,000 miles, a sea-coast of 3600, and lake-coast of 1200. They extend from latitude 25° to 49° north, and from longitude 66° 50' to 124° west; the greatest length being 3000 miles, and greatest breadth about 1170. The area, including Texas, California, and the still unorganised territories, is vaguely estimated at 2,220,000 square miles, with a population of 18,000,000, of whom 17,068,858 belong to the Union Proper.

The *United States* were originally British colonies, but in 1776 declared themselves independent. At that time the territory extended only from the Atlantic to the Mississippi: all the country to the west of that river belonged to France; Florida to Spain; and Texas to the Mexican Confederation. In 1803, Louisiana or the French territory was added by purchase; in 1819 Florida was ceded in compensation for spoiliations on American commerce; in 1842, Texas (which had revolted from Mexico in 1835, and erected itself into an independent republic) became part of the Union by voluntary annexation; and in 1848, California, which had revolted from Mexico in 1836, also joined the Union, thus giving to the States a seaboard on the west almost as valuable as that which forms their eastern boundary. The only states in the Confederation at its first formation were the thirteen marked with an \* in the annexed table; all the rest have been formed out of the new territories, and partly by subdividing the original thirteen:—

States.	Sq. Miles.	Population.	Chief Towns.
<i>Northern—</i>			
Maine, - - -	33,400	501,798	Augusta.
Now Hampshire,*	9,500	284,574	Concord.
Vermont, - - -	9,700	291,948	Montpelier.
Massachusetts,*	7,900	737,699	Boston.
Rhode Island,*	1,251	106,890	Providence.
Connecticut,*	4,979	309,978	Hartford.
<i>Middle—</i>			
New York,* - -	46,220	3,423,921	Albany.
New Jersey,* -	7,948	573,306	Trenton.
Pennsylvania,* -	46,215	1,724,023	Harrisburg.
Delaware,* - - -	2,068	78,085	Dover.
Maryland,* - - -	10,755	470,019	Annapolis.
<i>Southern—</i>			
Virginia,* - - -	65,700	1,229,797	Richmond.
N. Carolina,* - -	51,632	753,419	Raleigh.
S. Carolina,* - -	31,665	394,898	Columbia.
Georgia,* - - -	61,683	691,392	Millidgeville.
Alabama, - - -	54,084	590,756	Tuscaloosa.
Mississippi, - - -	49,356	375,651	Jackson.
Louisiana, - - -	47,413	352,411	New Orleans.
<i>Western—</i>			
Ohio, - - -	40,500	1,519,464	Columbus.
Kentucky, - - -	40,023	779,828	Frankfort.
Tennessee, - - -	41,732	639,210	Nashville.
Michigan, - - -	60,637	212,967	Detroit.
Indiana, - - -	35,696	685,856	Indianapolis.
Illinois, - - -	56,806	476,183	Springfield.
Missouri, - - -	70,050	383,702	Jefferson City.
Arkansas, - - -	54,617	97,574	Little Rock.
<i>District of—</i>			
Columbia, - - -	100	43,712	WASHINGTON.
<i>Territories—</i>			
Florida, - - -	56,236	54,477	Tallahassee.
Wisconsin, - - -	92,930	90,945	Madison.
Iowa, - - -	178,786	43,112	Iowa City.
Texas, - - -	100,000	100,000	Austin.
Oregon, - - -	...	...	Astoria.
California, - - -	...	...	San Francisco.

The territories of Florida, Wisconsin, and Iowa, formed in 1836, are under regular governments established by Congress, but not yet admitted as independent states; Texas retains, we believe, its own republican

administration as adopted in 1835. With respect to the unorganised territories, that on the Kansas has been given to the natives for a permanent abode; and within the last twenty years many thousand Cherokees, Creeks, Choctaws, and other tribes, have been carried thither, from east the Mississippi, with a pledge that they shall not be again compelled to remove. The Missouri territory is almost exclusively occupied by the wild Pawnees, Blackfeet, and other Indians; the Oregon, lying between the Rocky Mountains and the Pacific, and lat. 42° and 49° north, is also chiefly occupied by natives, with a sprinkling of trappers, and others connected with the fur-trade forts of the Hudson's Bay Company, and a few straggling settlers since the boundary settlement in 1847; and California, the youngest member of the Union, though possessing a sort of independent government before the treaty of union in 1848, is in reality an unorganised region inhabited by native tribes, hunting and trapping adventurers of Spanish origin, and latterly of adventurers of every character and description in search of gold ore in the alluvial deposits of its rivers.

Population.

The dominant population, as already stated, are of European origin. Those of *English* descent are found chiefly in the eastern states, Virginia, and the Carolinas; the *Germans* abound in the middle states, particularly Pennsylvania, where they constitute three-fourths of the population; the descendants of the *Dutch* are numerous near the Hudson and Mohawk in New York, of which state they were the original settlers; the *French* still form nearly half the inhabitants of Louisiana; the *Irish* and *Scotch* are numerous in the western parts of Pennsylvania, Virginia, and the Carolinas, and in most of the large cities of the Union; the *Negroes* are found chiefly in the states south of Pennsylvania and the river Ohio; parties of *Spanish* descent are to be found in California and Texas; and the native *Indians*, amounting perhaps to 500,000, are now entirely west of the Mississippi.

The rapid increase of population in the United States is one of the most interesting circumstances connected with their history. When the general style of living among any people is comfortable, and they continue at the same time to add rapidly to their numbers, it is a proof that their country affords abundant resources for subsistence, and that they have industry and skill to turn these to good account. England doubles the number of her people in about one hundred years, Scotland in one hundred and fifty; in America they are doubled in about twenty-five years; and it is reckoned that, by the end of a century from this date, if the same increase continues, the American population will be more than 200,000,000—a number greater than that of any nation at present speaking one language on the face of the earth. From the rapidity with which successive generations come forward, it is generally remarked that the number of aged persons in any neighbourhood appears small compared with the multitudes of young people by whom they are surrounded; and from the same reason the number of individuals below sixteen, who in other countries form hardly a third of the population, are in America fully one-half of the whole. The population at successive periods has been given as follows from the official census:—

	Population in 1790,	White People.	Blacks.
...	1800, - - -	3,929,837	697,897
...	1810, - - -	5,305,925	893,041
...	1820, - - -	7,239,814	1,191,264
...	1830, - - -	9,633,121	1,338,664
...	1840, - - -	12,866,920	2,009,031
...	1840, - - -	17,068,353	2,487,355

These returns show an average increase of 33 per cent. in ten years—a rate incomparably greater than has ever been witnessed in any other country. The number of persons who come from Europe to settle in the States is estimated variously, from 8000 to 12,000

or 16,000 yearly; the most accurate accounts incline to the former statement.

As might be expected, many of the cities in the Union have risen with unparalleled rapidity, and now contain large populations. Thus the population of New York in 1830 was 208,007; in 1840, 812,710; and in 1845, 871,102; Philadelphia in 1830, 167,118; in 1840, 258,037; Baltimore in 1830, 80,625; in 1840, 134,879; New Orleans in 1830, 46,810; in 1840, 102,193—that is nearly trebling its inhabitants in ten years: Boston in 1830, 61,392; in 1840, 98,883; and in 1845, 114,366; Cincinnati in 1830, 24,881; in 1840, 46,338; and Brooklyn, the last example which we shall give, 12,042 in 1830; 36,253 in 1840; and 59,566 in 1845!

#### Government—Army—Navy.

Each of the English colonies, as they settled in America, had had a certain form of government assigned it for maintaining the necessary order. This consisted generally of a House of Assembly, chosen by the people, with governor, judges, and other officers, appointed by the king, but paid out of taxes levied by the representatives. On acquiring independence after their war with the mother country, the different colonies, now called *States*, made such alterations, each in its own constitution, as they believed to be suited to their circumstances; and a general government, framed and appointed by the consent of the whole, was formed to take charge of such national affairs as the states could not manage separately. The States have each a Senate and House of Representatives; the members of the former are fewer in number than those of the latter, and a part of them only is chosen at each election, so that they remain in office for several years, generally four: the House of Representatives is elected anew every year. The resolutions agreed to by these two bodies for the government of the state, are afterwards submitted to a president or governor, whose sanction constitutes them part of the law. Both senators and representatives are paid for their attendance on the public business, generally at the rate of two dollars (or 9s. sterling) per day, besides an allowance for travelling expenses. The right of election resides in the people under certain limitations: in some states the possession of a certain property (about £50) is required in the electors; in others, the regular payment of certain taxes: in all, a residence in the state varying from two years to six months, is requisite. But there are only eight of the states in which black people are allowed to give votes. The judges and other magistrates are in some states elected by the people; in others, by the governor, subject to the approval of the two Houses: and their tenure of office is in some for a term of years; in others, during good behaviour; and in several, till the holder attain a certain age (about 70).

The general government of the United States is, like that of the states individually, a representative democracy, in which the people intrust the administration of affairs to executive and legislative officers of their own choice. At the head of the executive is a President, who, with a vice-president, is elected every four years, and must be a native-born citizen of the States. The legislative body consists of two Houses—the Senate and House of Representatives. The members of both Houses receive 36s. per day, with travelling expenses. The Senate is composed of two from each state, chosen by its legislature for six years. The members are required to be at least thirty years of age, to have lived nine years in the United States, and to be at the time of election residents in the state by which they are returned. The House of Representatives is chosen annually, and the members are required to be at least twenty-four years of age; to have resided three or four years in the state for which they are chosen; and, in one or two of the districts, to possess a certain property. There is one representative nearly for every 40,000 persons, five black men being reckoned in this enumeration equal to three white. The House of Representatives performs the duties allotted by the British

constitution to the Commons' House of Parliament, and has the right, like them, of originating all bills for raising revenue; while the Senate, on the other hand, exercises the analogous functions of our House of Lords. Bills which have passed the two Houses have not the sanction of law till they are signed by the president, or, on his refusal, are voted a second time by two-thirds of each of the Houses. The President, Senate, and House of Representatives, are called the *Congress* of the United States, and their powers in making regulations concerning public affairs are defined and limited by the original articles of the constitution. Congress is prohibited, for example, from making any law concerning establishment or free exercise of religion, the liberty of the press, and freedom of speech, or the privilege of public meetings to express their opinions on the measures of government.

The judicial power is vested in one supreme court, and in such inferior courts as Congress may from time to time establish. The supreme court consists of a chief-justice and six associate justices, who hold a court in the city of Washington annually; besides which, each judge attends in certain districts to hold circuit courts with the local justices. The processes of law are in general simple and direct, and are not made difficult of access to the poor by any burdensome expenses.

According to the constitution, all men are equal, none possessing any hereditary rank over the other; but this universal and broadly defined principle of democracy is impaired by the circumstance of there being upwards of 2,400,000 blacks forcibly detained in the condition of slaves, besides upwards of 300,000 of a free coloured population, who are shunned as an inferior race, and denied various social advantages. The constitution is further defective in practice, by being evidently incapable of restraining popular violence; for it is an incontestable fact, that mobs frequently defeat the operation of the law, when distasteful to their feelings, and commit flagrant acts of severity upon individuals. Perhaps a better state of education may remedy this great grievance; meanwhile, it is too important a feature in the political condition of the people to be passed over in silence. Generally speaking, it may be said that popular opinion is the absolute governing power in the States, and cannot be withstood by any species of opposition. Popular opinion, whether right or wrong, enforces uniformity in external behaviour and profession of belief to a degree which would be denounced as despotic if exercised in a monarchical country.

The expense at which the entire government of the States is conducted, including the military and naval departments, is on a singularly economical scale. In 1846 the gross revenue of the States amounted to 29,499,247 dollars,\* and the expenditure to 28,031,114; in 1847 the revenue was 26,346,790 dollars, and the expenditure (augmented by the war with Mexico) 59,451,177. In 1846 the national debt was 24,256,495 dollars; in 1847 it was increased to 45,659,659, at an annual interest of 1,059,039 dollars. The chief source of revenue is the customs, amounting in 1846 to 26,712,667 dollars, and in 1847 to 23,747,864; and the sales of public lands, amounting to 2,694,452 dollars in 1846, and to 2,498,355 in 1847. The chief items of expenditure are the civil list, which in 1847 amounted to 2,562,008 dollars; foreign intercourse, 391,115 dollars; miscellaneous, 3,762,732; military establishment, 13,679,428 dollars in 1846, and 41,281,606 in 1847; naval establishment, 6,450,862 in 1846, and 7,931,638 in 1847. The increase of expenditure in 1847 is fully accounted for by the war with Mexico: this also added considerably to the national debt, as several loans had to be effected; but as this war has now terminated, Mexico repaying the expense, and as the land sales are again on the increase, not only will the revenue

\* The standard currency of the States is in dollars, silver coins worth about 4s. 3d. sterling each; each dollar is equal to 100 small copper coins called cents, from *centum*, a hundred.

exceed the expenditure, but a considerable portion of the debt be annually cancelled.

The *army*, according to the law of 1842, consists of 9000 men; but the principal reliance of the country for defence is in the militia of the several states, amounting altogether, in 1848, to 1,888,588 men. In this body the men acquire a certain knowledge of military exercises, but submit very little to subordination. There is a military academy for educating young men as officers; the number under tuition is limited to 250; and the instruction given is well fitted for training their minds to knowledge and gentlemanly feelings: the course consists of natural and experimental philosophy, mathematics, engineering, ethics, drawing, and the usual military exercises. The young men educated here are received into the army as cadets, and their promotion is afterwards regulated strictly by seniority, except in extraordinary cases.

The *navy* consisted in 1848 of 11 ships of the line, 12 frigates of 44 guns, 2 frigates of 36 guns, 22 sloops of war, 4 brigs, 10 schooners, 5 bomb-vessels, 14 steamers, and 6 store-ships and brigs. The number of captains in the same year was 67, commanders 97, 327 lieutenants, and midshipmen 428. Besides the regular navy, there is also a *marine corps*, consisting, in 1848, of 58 officers and 1365 men. There are seven navy-yards, of which the principal are on Long Island, near New York, at Philadelphia, and at Washington. Recent events may have caused an alteration in this summary of the military and naval force.

Religion and Education.

All forms of religion are equally favoured by the state in America, and the members of all have equal privileges. None of the clergy are paid by government, or out of public property, in any shape; they depend for their salaries entirely upon the congregations for which they officiate, and by which they are elected. The bishops, ministers, elders, or other officers, are chosen by the members of each persuasion, according to their several forms of church government, without the intervention of any other party. There are a great number of different denominations of Christians in America; the principal are the same as in this country, consisting of Catholics, Protestant Episcopalians, Presbyterians, Quakers, and the various classes of Independents. In some of the states there are certain denominations more prevalent than others. New England, for instance, was settled by the Puritans in Cromwell's time, and its religious condition bears the impress of that origin. Maryland was colonised by Roman Catholics, who are still numerous there: Pennsylvania by the Quakers or Friends; while Episcopacy prevailed in Virginia, the Carolinas, and Georgia. The first Presbyterians came from England, Scotland, and Ireland, and settled in Delaware and New Jersey. If the whole population of the States were divided into twelve parts, three of them would be Calvinists, chiefly of the Independent and Presbyterian sects; two Baptists; two Methodists; one Episcopalians and Lutherans. The rest include persons of many various forms of belief, and a considerable number who follow no definite or recognised religious profession.

There are about sixty colleges and seminaries for the education of young men devoted to the church, of all the different sects. In New York, it is found that there is 1 clergyman to every 1384 of the population; in Pennsylvania there is 1 to every 1123; in Kentucky, 1 to every 1877 of the white inhabitants. In Great Britain, the proportion is 1 to every 800 or 900—in Europe generally, 1 to every 1000. It must be recollected, however, that in America this whole number are actually employed in the ministry: there are none of them who are merely dignitaries, or who hold offices without labouring for the instruction of the people: this renders the proportion of actual religious teachers greater than at first sight it appears, when compared with the number of clergymen in European countries.

The remarks we have here made apply exclusively

to the New England states, and to the older settled districts of the east; they may also perhaps be extended to the *towns* of the newly-formed western states, in which much attention is given to religion. In the slave countries, however, this condition is altogether reversed. North Carolina, with a population of 600,000, has hardly fifty clergymen; and South Carolina, with 420,000 inhabitants, has not more than forty. In Georgia there were only ten in 1818. In Virginia, the population is about 1,000,000; the number of clergymen not 100. The situation of Maryland is similar.

In the countries on the Ohio, Michigan, &c. which are in progress of settlement, there are no regular churches except in towns; the only opportunity the colonists have of attending sacred ordinances being at field-meetings, which are held in the forests, and are sometimes continued for several days. The first settlers in these districts are generally rude men, and little heedful of religious matters; but these meetings serve to keep alive among them a feeling of what is due to their character in this respect, and, as the population becomes more dense, gradually lead to the establishment of regular pastors and churches.

The state of the people in respect to education is very different in different parts of the States. In the old settled districts, the proportion of well-informed and well-educated people is greater than in most countries of Europe. In the slave states of the south; and in the western districts, which are as yet only occupied by a thinly-scattered population, the number who can read and write is very small in proportion to the population. Some idea of these different conditions in respect to education, may be formed from the following account of the number of students at college in the different districts in proportion to the whole inhabitants of each:—

In the eastern or free states, 1 student to 1231 inhabitants.		
... middle slave states, 1	... 3465	...
... southern slave states, 1	... 7232	...
... western or new states, 1	... 6060	...

According to the census of 1840, there were 173 universities and colleges (including theological and medical institutions), with 16,233 students; 3242 academies and grammar-schools, with 164,156 students; and 47,209 common and primary schools, with 1,845,244 scholars—or about 1 in 9 of the entire population. In 1848, there were within the Union 118 colleges, with 897 professors and 10,898 students; 42 theological schools, with 118 professors and 1317 students; 12 law schools, with 21 professors and 885 students; and 36 medical schools, with 238 professors and 4727 students.

In the New England states the means of instruction provided for the children of the labouring classes are in general such as to put the knowledge of reading, writing, and arithmetic, within the reach of all. Every state has a public fund set apart for paying the salaries of teachers; and if this is not sufficient to provide one for each township, the inhabitants are expected to assess themselves to make up the deficiency. They generally elect school-committees, who build school-houses, choose teachers, and apportion funds, according to the necessities of each parish. Children are entitled to attend at these seminaries without any charge but that of paying for the books which they use. In order further to secure the education of young people who may be obliged to go early to *service*, it is common in these states to stipulate *schooling as part of their wages*. The result of all this is, that the number of people of the working-classes who can read and write is here fully greater than in any country of Europe, not even excepting Scotland or Switzerland. The means of education are seldom wanting, while the wages of the labouring classes enable them to provide books, and to maintain their children at school for a longer period than can be easily done in Europe, where their services are soon required to assist in maintaining the family. It is remarked, that 'though the number of learned and scientific characters is much smaller than in France

of England, the mass of the population are better informed than in either of these countries. Reading the journals universally, and knowing a little of what is doing at home and throughout the world generally, they betray none of that awkwardness which springs from conscious ignorance.

It must not be supposed, however, that this general account of the state of education applies equally to every district. It relates, indeed, chiefly to the great towns, and to the thickly-peopled places in their neighbourhood. The remote townships, which in a country so lately occupied form a large proportion of the whole area, are frequently as much deficient in the means of instruction as in regard to religious edification; and they have indeed little anxiety to improve themselves. Many of them pay no attention to the regulations for establishing schools, and, were it left to themselves, would allow their people to remain as they are, without either reading or writing. In America, however, as in most other free countries, the well-informed portion of the community is the most active, and, like the little leaven which leavens the whole lump, it is continually at work to stir up a desire for information and light in all the dark places around it. In all the newly-settled states, lands have been allotted for the erection of academies, and the establishment of regular district or parochial schools, according as the population increases; 640 acres are generally set apart in each township for this purpose, besides one or two entire townships in each state for university funds.

#### Minerals—Mining.

There is a great variety of useful minerals distributed through different parts of the States. Coal may be mentioned among the first: it exists through all the country, lying north of a line drawn from Philadelphia to the mouth of the Ohio, and is particularly abundant on the upper waters of the Susquehanna, as well as on the Alleghany and the Monongahela. At Pittsburg there is a hill principally composed of coal, and it is found at many places in this district within a few feet of the surface. There are extensive coal-mines also on the Roanoke and Appomattox in Virginia. In 1840 there were raised in the States 27,603,191 bushels of bituminous coal; and 863,489 tons of anthracite.

The country on the Ohio is particularly rich in mineral productions. The whole district is bottomed on limestone, on which rests the wide and valuable coal formation mentioned above, extending from the head waters of the Ohio, in Pennsylvania, to the river Tombigbee. Iron ore is found abundantly in the same district, principally towards the upper part of the Ohio; bog ore is found in the valleys of the Alleghany chain; and various kinds of ores of the same metal are met with in the New England states. In 1840 there were produced 286,903 tons of cast-iron, and 197,253 tons of bar-iron. Black lead, in veins of from five to six feet wide, traverses the states of New York, Jersey, Virginia, Carolina, &c. Copper ore is found in Virginia, in Connecticut, in New Jersey, and abundantly in the neighbourhood of the lakes, and in Illinois.

Gold mines have been traced extending through a large tract of country in the western parts of Virginia, North and South Carolina, and Georgia: they are wrought to a considerable extent, 20,000 men being employed at the different workings. The annual produce varies widely—ranging from £120,000 to thrice that amount; but we have not heard what proportion of this is expended in the work, or what actual profit has been realised. One singular fact is remarked concerning these mines, which is, the indubitable evidence found that they have been wrought at some period before America was known to the Europeans. Many pieces of machinery which were used for this purpose have been discovered in the workings, among which were several crucibles of earthenware, which are far better than those now in use. Since 1848, the gold diggings of California have thrown the mines of the southern states, as well as those of every other

region, in the shade; the produce is evidently immense, but current reports are yet too vague to be of anything like statistical value.

Silver and its ores are not of frequent or extensive occurrence. Mercury has been found native in Kentucky, but it occurs plentifully in the ore as bituminous cinnabar, through the Ohio and Michigan territory. It is found in the soil as a black or red sand, sometimes as a fine red powder, and at other times in iron clay. There are lead mines of vast extent on the Missouri; they are said to occupy a surface of 600 miles in length, and 200 in breadth. One miner will raise about 2000 lbs. per day, which sell for 45 dollars, and yield 1200 lbs. of pure lead. In 1840, the amount of pig lead exceeded 31,200,000 lbs.

Epsom salts, Glauber salts, and nitre, are found in Ohio and Indiana; the two latter in caves, the former in a thin layer on rocky surfaces. Salt, which in countries far removed from the sea is an article of great expense, is produced from salt springs, or from borings in different parts of the western country. Mineral waters of valuable medicinal qualities occur at several places; the springs principally frequented are those of Saratoga in New England.

#### Agriculture and Crops.

In point of productive industry the United States is yet more an agricultural than a manufacturing country, though of late years an immense impetus has been given to the latter department. Oats, rye, and barley are raised in all the northern states, and also in the hilly districts of the south. Of barley, two crops in a season are obtained in favourable situations. Maize is common to every part of the Union, but thrives best in the middle states; it is a vegetable adapted to a greater variety of soil and climate than wheat, and yields a much larger produce. The sugar maple grows everywhere, but thrives best in the good maize districts. Wheat is also cultivated through the whole Union; but it is only a profitable crop to the north of the Potomac, or in the hilly districts of the south; in these situations it yields large returns, and of excellent quality; in the low warm districts it is not cultivated; these are more favourable to the rice crop. In general, it is remarked that the late wheat countries are favourable to the European constitution, and that in rice countries, which are warm and moist, the African population has a great advantage in respect to health and longevity over whites.

The cultivation of tobacco begins in Maryland, in latitude 39°; it is raised to a greater extent in that state and in Virginia than in any others of the Union; but it thrives also in all the western states. Cotton does not succeed well farther north than the latitude of 37°, though some of the districts raise it for domestic use; it forms the staple of all the districts south of the river Roanoke. The best kinds grow in South Carolina and Georgia, in dry situations, upon the sea-coast. The cultivation of rice occupies nearly the same region as that of cotton; it is a very unhealthy occupation for the slaves who are engaged in it. The climate which is favourable to sugar does not extend beyond the latitude of 32°; it is raised in the States chiefly for domestic use, and is not an article of export to any extent. The crop is rather precarious, from the frosts which sometimes occur even in the most southerly districts. Indigo has been tried in America, but could not come into competition with that of Bengal. The vine grows spontaneously in most of the southern and western states, and is cultivated as a fruit about Philadelphia. The mulberry-tree, hops, and hemp, all succeed well in the middle and western states.

The timber-trees of the States are of numerous kinds, and many of them of the best quality. There are twenty-six kinds of oak, of which eleven or twelve species are in request; the best for common purposes is the *white oak*, a tree which is found plentifully over the whole country; the *live oak* grows in marshy places near the sea, and has a hard, heavy, and durable timber,

much used for shipbuilding. There are eighteen kinds of pine, cedar, and larch; seven kinds of maple, three or four of which furnish sugar—the best is called the sugar maple; ten kinds of walnut-trees; four kinds of birch, the bark of one of which furnishes the Indians with canoes; six kinds of ash (the ash of this country is not of the number); besides many other trees, of very useful qualities. There are one hundred and thirty kinds which rise to a height of more than thirty feet; while in France there are only thirty-seven of that size. The flowering shrubs, *balms* and *rhododendron*, which are cultivated here with so much attention for their splendid flowers, grow wild on the sides of the American hills, to the height of fifteen or twenty feet. Even in the most thickly-peopled states there are still remaining large tracts of uncleared woodlands, which give the country a wild appearance, and form an aspect on the whole very different from anything seen in Europe, where forests have long been too valuable to be allowed to remain uncut.

The crops of the chief cultured articles in 1840, and the states ranking highest in production, were as follows:—Indian corn, 377,531,375 bushels—Tennessee, Kentucky, Virginia; wheat, 84,822,272 bushels—Ohio, Pennsylvania, New York, Virginia; oats, 123,071,341 bushels—in the same states; rye, 18,645,657 bushels—Pennsylvania; barley, 4,161,504 bushels—New York; potatoes, 108,298,060 bushels—New York and Maine; hemp and flax, 95,252—Virginia; rice, 80,841,420 lbs.—S. Carolina; tobacco, 219,168,319 lbs.—Virginia, Kentucky; cotton, 790,479,275 lbs.—Mississippi, Georgia, Louisiana, and Alabama; sugar, 115,110,809 lbs.—cane in Louisiana, and maple in the north; and silk, 61,522 lbs.—Connecticut. In the same year, the live-stock was estimated at 4,335,669 horses and mules; 14,971,586 neat cattle; 26,301,293 swine; and 19,311,374 sheep.

Manufactures.

The vast extent of cultivable and prolific land in the United States, and the constant demand for large supplies for food, form a reason why the nation should resort more to agriculture than manufacturing industry as a staple employment. The Americans, nevertheless, from a strong desire to be independent of foreign countries for a supply of articles of clothing, have thrown themselves energetically into a course of manufacturing in relation both to soft and hard goods. At present they are engaged in a kind of rivalry with Britain, and it is certain that they are fast overtaking it, both in the excellence and cheapness of their products.

The manufactures which are followed with most advantage in America, and without fear of English rivalry, are those which produce articles too bulky or too heavy, in proportion to their value, to bear the expense of a long carriage, or of which the materials are found in the country, and can be wrought up there at less expense than by carrying them to cheaper tradesmen at a distance. Some of these branches may be mentioned—such as the making of soap, candles, and hats; tanning and working in leather, particularly bulky articles; building of carriages; making of all kinds of agricultural implements; carpentry, sawing, and turning of most descriptions; building of ships and steamboats; constructing and putting up of mill-work and machinery; distilling; the employments of goldsmiths, tinsmiths, and printers. There are several businesses, however, whose prospects depend chiefly on prohibiting the cheaper manufactures of England, and which of course are liable to be deranged by any alteration in the tariff laws: these are the making of glass and earthenware; spinning and weaving most kinds of cotton goods; making of woollens, carpets, &c.; most of the finer kinds of hardware, iron, steel, and brass; hempen goods and silk goods.

Within the last few years the manufacture of cotton has been conducted on a great scale by means of factories on the same plan as those in England. The cotton manufacture was introduced only in 1790, and in 1852

it was found that the number of mills in twelve states was 795, of spindles 1,246,503, of power-looms 33,506; of males employed in the manufacture 16,539, females 38,927—total employed, 57,466. The amount of capital now invested in this thriving branch of trade, is estimated at 50,000,000 dollars, equal to £10,000,000 sterling, being about a fourth part of the capital invested in the cotton manufacture in Great Britain. By procuring the cotton cheaper than can be done in England, the Americans have an important advantage; wages, however, are higher. The principal cotton manufacturing districts are in Massachusetts, Maine, and other states on the coast. The chief seat of the manufacture is Lowell in Massachusetts, and it may be termed the Manchester of America. Besides containing at least a dozen factories for cotton and woollen fabrics, Lowell possesses large machine-making establishments, which employ many hundreds of workmen.

Household manufactures of woollen, linen, and cotton, are made to a great extent. Many families spin, weave, and make up their own clothing, sheeting, table-linen, &c. They purchase cotton, and mix it up in the yarn with their linen and woollen stuffs; blankets, quilts, coverlids, stockings, mits, &c. are made chiefly in the family. These are perhaps neither so fine nor made so expeditiously as those of regular tradesmen; but they are produced for domestic use at times when there is no other employment, and in this manner may be said to cost nothing except the material of which they are made. It is supposed that nearly two-thirds of the domestic clothing is so made in country places, many families, as in Canada, having a loom in the house. It is the same with soap, candles, and maple-sugar, all of which are manufactured by the farmers at home. Attempts have recently been made, with great success, to introduce the manufacture of silk; the mulberry-tree grows spontaneously in the middle states, and the light easy labour which the collecting of the silk requires would afford employment to old people and females, enabling them to add to the income of their families, when they could not otherwise be able to do anything. Distillation and brewing are conducted upon a large scale, there being not less than 41,402,627 gallons produced in 1840; and a little wine is made in North Carolina and other places. Shipbuilding is extensively followed in Maine and Massachusetts. In 1848, there were 1598 vessels of all sorts built within the Union, having a tonnage of 243,732.

In the southern states there is little manufacturing; the inhabitants there depend on the northern states or on foreign countries for their supplies, and their exports are cotton, sugar, and other raw materials.

Commerce.

The wealthiest class in the United States is generally the merchants of large seaport towns. Commerce may be considered as forming the aristocracy of that country, and is regarded everywhere as highly honourable. Young people are educated for it with as much care as for the army, or for any of the learned professions. The manufactures and markets of foreign states—the quality, value, and profits of every commercial article—form the objects of their study, and prepare them for engaging in business with system and advantage. The same energy of character which has brought English commerce to the highest pitch, is carrying forward the United States in a similar career, but perhaps with undue speed. The chief fault of the American commercial character is an over-haste to be rich. This 'go-ahead' policy leads to wild speculations, on an extensive scale, which produce most disastrous results on the currency and finances of the nation. At an interval of every few years, the banks suspend payments of their notes in cash; debts due to foreign merchants and others cannot be liquidated, and money is scarcely to be had.

In the year ending June 1847, 14,229 vessels, with a tonnage of 3,321,705, entered the ports of the United States, and 14,370 vessels, with a tonnage of 5,378,998,

## NORTH AMERICA.

cleared out. Of this vast amount of shipping more than one-half belonged to the country—the number of American vessels entering being 7730, with a tonnage of 2,101,359, and of those clearing out 8102, with a tonnage of 1,220,346. In the same year, the gross imports of the Union amounted to 146,545,638 dollars, and the exports 158,648,622: of which 150,637,462 consisted of the growth, produce, and manufactures of the States. The largest items of export were—cotton, yielding upwards of 53,000,000 dollars; flour, 26,000,000; Indian corn, 14,000,000; tobacco, 7,000,000; pork, bacon, lard, and live hogs, 6,600,000; cotton piece goods, 4,000,000; rice, 3,600,000; and beef, tallow, hides, and horned cattle, 2,400,000.

The immense number of navigable rivers which run through the country in every direction, and discharge themselves into the ocean or the lakes, afford the means of a great internal trade. These facilities have been increased at many important points by canals, connecting the different rivers at points where they approach each other, or where they flow away in opposite directions from sources lying in the same neighbourhood. Between the southern and eastern states there is a constant interchange of commodities along the coast, and a similar trade goes on from the western states to the south, by the Ohio and its branches, down the Mississippi. New Orleans is the great entrepôt for the goods of the latter branch of internal commerce. The north-eastern states furnish rum, molasses, cordials, dried fish, European goods of all descriptions, and articles of small value, quaintly styled *notions*; and they take in return corn, grain, cotton, and tobacco, from the south; while from the western states are received hams, beef, lard, flour, &c. either for use or for exportation to the West Indies and the other parts of Southern America. The traffic from north to south along the coast is greater than might be inferred, even from this specimen of internal trade by the rivers; because the productions of the northern and southern districts on the sea-coast are as different from each other as those inland, while the states in that part of the country have been longer and more densely peopled. In 1848, there were upwards of 4000 miles of canal navigation; and upwards of 10,000 miles of railway chartered, of which about 5703½ were open. The roads, excepting those of New England, and the national one from Baltimore to St Louis on the Mississippi, 700 miles long, are very indifferent, being little better than forest tracks.

### Peculiarities of Different Districts.

America is generally considered and spoken of as one country, its people as forming a single nation, and the remarks which are made with regard to one part of it are supposed to be equally applicable to all. No idea, however, can be more fallacious. The region which we term the United States is composed of sections of country as remote from each other as London is from Constantinople, or Madrid from Berlin: they lie under different climates, and the different circumstances under which their inhabitants are placed form in each a totally different set of manners. The English language is common to all, and they all profess the Christian religion; but in most other respects the difference between them is as great as between any two European nations. The great divisions under which the country ought to be viewed are the north-eastern or New England states, in which for the present may be included Pennsylvania; 2d, The southern or slave states, to which section also we may refer Kentucky and Tennessee; and 3d, The new states of the west, which are in progress of settlement. The manners of the New England states are formed on the model of those of our own country, and there are few circumstances in the nature of the climate which tend to produce any material alteration; it is among them only that due provision is made for the education of the people or for religious instruction. The productions of the soil—the modes of agriculture—the arts and occupations to which these give rise—the alternations of season—and many other things, have

all a resemblance to those of our own country. They cultivate wheat and the other European grains; their garden vegetables, potatoes, turnips, carrots, cabbages, &c. are the same as ours; they employ the same domestic animals; and they use of course the same agricultural implements, the same grist-mills, &c. requiring also the same tradesmen to prepare and work them.

Even in these great divisions which we have pointed out, there are portions which differ exceedingly from each other. New Orleans, for instance, which belongs to the slave states, has a completely different set of manners from Charleston in Virginia. The former is a city of immense trade, situated at the mouth of the great river Mississippi; it contains a mixed population of blacks of all shades, and of white men from every nation in Europe. Its streets are crowded and speckled with people of every colour; its quays with ships of every country; and its wharfs are loaded with bales of goods from all quarters of the earth; some coming from Europe or from China, to be carried for three thousand miles up the inland rivers of America; others sent down these rivers some months' voyage, to be carried to the West Indies or the Mediterranean. The air of the place is unwholesome, and it is a mart where people hurry to make money before they be overtaken with disease and death. Such are the influences under which the manners and character of the people of New Orleans are formed. Charleston, on the other hand, is the capital of a wealthy agricultural state; the pursuits of the people are not decidedly commercial; the town is the resort of numerous country gentlemen, who pride themselves rather on the oldness and respectability of their families, and the extent of their property, than on the activity of their business habits. The gentry strive to keep up between themselves and their slaves an exterior resemblance to the feudal relations of Europe; coats of arms are fashionable, as are liveries for servants: there is a general air of elegance and splendour in the buildings of the town: some of the houses are real palazzos, surrounded with orange trees, magnolias, and other trees of an almost tropical climate. There is considerable taste for the fine arts among the higher classes, and among the lower an absence of all that bustle and variety of language and dress which mark a great commercial city. It is obvious, therefore, that the manners of these two places can have very little in common.

If we glance at the northern states, we shall find a difference of a similar kind existing between New York and Philadelphia. The former city is the great thoroughfare of all emigrants and commercial agents who arrive from Europe; the people passing through it daily are sometimes estimated at 15,000 or 20,000; it lies at a central point, having communication by rivers, canals, and railways with the whole northern parts of the American continent. Grain, provisions, lumber, and manufactures are brought from countries a thousand miles inland, for exportation, or for the use of places along the coast which have not the same facility of conveyance. People arriving there are secure of finding a passage to every other city inland or coast-ways; hence the streets and quays are constantly crowded with travellers and their luggage. The extent of its commercial transactions gives a facility to those who wish to engage in any kind of speculation, because here they can always learn the prices or the demand for every article of American produce; hence there is a restlessness, bustle, and continual spirit of change among its population, or a great part of it, which it would be vain to seek elsewhere in Europe or in America. Philadelphia, on the other hand, though also a place of very extensive commerce, has fewer channels of communication with the distant inland countries, and has of course a smaller variety of produce either raw or manufactured: hence there is less speculation; business proceeds with more steadiness, but less apparent bustle; there is in the streets an air of quiet regularity, where every one seems to go easily and leisurely about his business; and the transit of strangers through

the place is but inconsiderable. The prevailing religion, which is Quakerism, has also a manifest influence in producing these effects. The influence of circumstances upon the manners of a people is nowhere more remarkable than it is here in the case of the negroes. Slavery is not permitted in this state; and the inhabitants do not countenance in all its severity that feeling of contempt with which black people are regarded in other parts of the Union; hence the Africans reside here in freedom and comfort, while they see their countrymen a few miles to the southward poor degraded slaves; and they are generally, in consequence, a contented, cheerful, and industrious caste.

Again, if we look at the western states, we shall find that though there is a certain uniformity of manners over the whole, they are here also differently modified, according to circumstances. Pittsburg, for instance, with the neighbouring towns, Wheeling and Steubenville, are in the centre of a country which is rich in various kinds of minerals—coal, iron, lime, &c.; they are therefore filled with a manufacturing population, and the pursuits, appearance, and manners of their inhabitants differ from those of the country around them, as those of Birmingham may be supposed to do from other places in the centre of England. The town of Cincinnati, again, which is situated on the Ohio, as these places also are, is a great inland dépôt for merchandise to be exported or imported. Its inhabitants are merchants, attendants in counting-houses and warehouses, owners of river steamboats, and a population attracted by the general trade of the place; while there is also a large number occupied in the peculiar business of killing and salting for exportation the immense quantities of live-stock reared in the country.

#### MEXICO.

Mexico, occupying that portion of the North American continent which lies betwixt 16° and 42° north latitude, was conquered by the Spaniards, under Cortez, in 1521, and continued a colony of Spain till 1821, when it became an independent republic. From 1821 to 1835 the states were severally independent, but united into one federal republic, like the United States; in 1835 they resigned their separate independence, and became a consolidated or central republic. Mexico originally comprehended Texas, which revolted in 1835, and is now part of the United States; California, which declared its independence in 1836, and in 1848 also joined the United States; and Yucatan, which seceded so recently as 1841. The area of the country, as thus diminished, is estimated at about 900,000 square miles, with a population of from 6,000,000 to 8,000,000—of whom about one-half are Indian aborigines, 1,250,000 whites, and the remainder mixed races. The Congress of the Union consists of a president, vice-president, and of two legislative bodies—the Senate and the House of Representatives. Capital, Mexico, with a population of 140,000.

Geographically, about one-half of Mexico lies within the tropics, while the rest belongs to the temperate zone; but a large proportion of the tropical region enjoys a mild temperate climate in consequence of its elevation—being from 6000 to 7000 feet above the sea. In the course of this tract, some of the heights already adverted to rise to the level of perpetual snow. 'The table-land (see Vol. I. p. 57) gradually declines towards the temperate zone; but the descent towards the coasts, especially the east coast, is by a gradual series of terraces, which produce an extraordinary diversity of vegetation, and at the same time oppose great difficulties to the communication between the maritime districts and the interior. In the equinoctial region there are only two seasons, the wet—from June to September—and the dry, which lasts for eight months; and in this district the different climates rise, as it were, one above the other from a temperature of 80° on the coast to 62° in the interior. The coast is humid, and unhealthy for strangers; but the table-land is remarkable for its salubriousness, and it is here that

the population is concentrated. The summit of the table-land is almost destitute of vegetation, but the other districts are generally productive. Maize is the chief object of culture; besides which, the banana, manioc, cereal grains, rice, and the potato form the common food of the people. The narrow insalubrious plain along the coast called the *tierra caliente*, or hot country, is remarkable for its luxuriant vegetation. The chief productions of this region are the sugar-cane, cotton, cocoa, indigo, and tobacco. The southern part of the country forming the isthmus is celebrated for the variety and importance of its woods and drugs, including logwood, caoutchouc, vanilla, jalap, storax, and the trees upon which feed the cochineal insect. Vast herds of horses, mules, and horned cattle also cover the plains of the southern district.

The mines of Mexico, however, constitute the chief source of its wealth, particularly those of silver, which are the most productive in the world. Gold is also to be found, though in lesser quantities; and copper, tin, iron, lead, and mercury occur in various districts. Manufactures are generally in a rude state; agriculture indifferently attended to; and trade and commerce incessantly injured and obstructed by the internal dissensions of the country. 'The Cyclopædia of Commerce,' from which we extract these remarks, estimates the exports (chiefly silver, gold, cochineal, woods, drugs, and dye-stuffs) at from £3,000,000 to £3,500,000 annually, but this must be taken as a mere approximation. As to the imports, there are no data whereupon to form any estimate: they consist chiefly of soft goods, hardwares, wines, brandy, and spices. Britain sends annually upwards of £450,000 of produce and manufactures; the United States about £150,000. The chief ports for foreign trade are Vera Cruz, Tampico, and Campeachy, in the Gulf of Mexico; and San Blas, Mazatlan, and Acapulco, on the Pacific seaboard.

#### CENTRAL AMERICA.

The United States of Central America, or, more briefly, the Central States, include that narrow tract of the continent which lies between Mexico on the north and the isthmus of Panama on the south—being about 1000 miles in length, and from 80 to 250 in breadth. Their area is estimated at 186,000 square miles, and their population at 2,000,000. The country was formerly the captain-generalship of Guatemala; but in 1823, the people adopted a constitution providing that the government should be vested in a Federal Congress, a Senate, and a President. The states constituting the confederacy are Guatemala, Honduras, Nicaragua, Costa Rica, and the federal district of San Salvador. The country is extremely diversified, well watered, fertile, rich in minerals, favourably situated for commerce, has numerous ports on both seaboard, and is altogether calculated to support a large and thriving population. The exports chiefly consist of specie, indigo, cochineal, brazil wood, and other articles of tropical produce, amounting to about £1,000,000 annually. The imports are cotton and woollen fabrics, hardware, and other dry goods from Britain; silks, wines, and trinkets, from France and Spain.

#### YUCATAN.

This state comprises the peninsular district situated between the Gulf of Mexico and the Bay of Honduras, containing an area of about 76,000 square miles, with a mixed population of 570,000. Till 1841, Yucatan formed one of the members of the Mexican Confederation, but the people then separated from the Union, declared themselves independent, and adopted a constitution on the most liberal political, religious, and commercial principles. In physical aspect, natural produce, and industrial pursuit, the country closely resembles Belize and Mexico already described. Besides some measure of modern importance, it also lays claim to considerable antiquarian interest, from the ruins of certain gigantic sculptured structures which are found at Oxmutal and other places. (See Vol. I. p. 435).

## SOUTH AMERICA.

THIS great division of the western hemisphere is a peninsula of a triangular form connected with North America by the narrow Isthmus of Panama. Projecting its apex far into the Southern Ocean, its western shores are washed by the Pacific, its eastern by the Atlantic, and its base by the Atlantic and Caribbean

Sea. It extends from latitude 12° north to 52° 30' south, or including the Archipelago of Terra del Fuego, to 56°—the small island called Cape Horn, in that parallel, being generally reckoned the extreme point of South America. Taken at its widest part—from Cape St Roque in Brazil, to Cape Blanco in Peru—it

extends from longitude 35° to 82° west. Its area is estimated at 6,800,000 or 7,000,000 square miles, of which about two-thirds lie within the tropics.

### SUPERFICIAL FEATURES—GEOLOGY.

The physical configuration of the continent is thus arranged by an American authority:—1. The low belt of country skirting the shores of the Pacific, from 50 to No. 70.

150 miles in breadth, and 4000 in length, of which the two extremities are fertile, and the middle sandy and arid. 2. The basin of the Orinoco, enclosed by two branches of the Andes, and consisting of extensive plains called *llanos*, either destitute of wood, or merely dotted with trees, but covered during part of the year with high herbage. 3. The basin of the Amazon, a vast plain, embracing a surface of more than 2,000,000

square miles, possessing a rich soil and humid climate, almost entirely covered with dense forests, and impenetrable jungle-marshes by the river sides. 4. The great valley of the Plata, occupied chiefly by open plains called *pampas*, in some parts barren, but in general covered with weeds, thistles, and tall grasses, on which feed prodigious herds of wild horses and cattle. 5. The high country of Brazil, eastward of the Parana and Uruguay, presenting alternate ridges and valleys, covered with wood towards the Atlantic, but opening into grassy steppes in the interior.

Everything in South America is upon a grand scale. The mountains, the rivers, the forests, the plains—every feature of nature, in short, is characterised by magnificence and sublimity, and calculated to excite alternately admiration and wonder. In one point are seen mountain-summits above the clouds, white with snows that never melt, while round their bases grow the banana and pine-apple. In other places are to be seen ever-living volcanoes, throwing out flames, smoke, ashes, and stones. Then, again, we have vast and dark forests, which never yet rang to the woodman's axe, where vegetation prevails in its most gigantic forms. 'In the interior of the new continent, says Humboldt, we almost accustomed ourselves to regard men as not being essential to the order of nature. The earth is loaded with plants, and nothing impedes their development. An immense layer of free mould manifests the uninterrupted action of organic powers. The crocodiles and the boas are masters of the river; the jaguar, the peccari, the dante, and the monkeys, traverse the forest without fear and without danger; there they dwell as in an ancient inheritance. This aspect of animated nature, in which man is nothing, has something in it strange and sad. To this we reconcile ourselves with difficulty on the ocean, and amid the sands of Africa; though in these scenes, where nothing recalls to mind our fields, our woods, and our streams, we are less astonished at the vast solitude through which we pass. Here, in a fertile country, adorned with eternal verdure, we seek in vain the traces of the power of man; we seem to be transported into a world altogether different from that which gave us birth.'

The *mountains* which traverse the continent may be ranked under two systems—the Cordilleras or Andes Proper, and the Brazilian Andes, so called from the Peruvian word *ant*, signifying copper. The former, in several parallel chains, extend from the Straits of Magellan to the Caribbean Sea, in many places spreading out over a breadth of several hundred miles, embracing lofty table-lands, containing mountain lakes, and everywhere intersected by steep narrow valleys, ravines, and lofty waterfalls. At Popayan, the main chain divides into three ridges, one of which, shooting off to the north-west, passes into the Isthmus of Panama; a second separates the valleys of the Cauca and Magdalena; and a third, passing off to the north-east, separates the valley of the Magdalena from the plains of the Meta. The highest summits of the system are between 15° and 17° south, where Sorata reaches the elevation of 25,350, and Illimani that of 24,200 feet; throughout Chili and Peru they range from 15,000 to 23,000 feet; in Colombia from 12,000 to 18,000 feet; and in Patagonia from 4000 to 8500. Altogether, the Andes present a most magnificent spectacle to the voyager on the Pacific; the snow, which permanently covers their lofty summits, even under the burning sun of the equator, contrasting beautifully with the deep blue of the sky beyond; while occasionally another contrast is exhibited in vast volumes of smoke and fire, emitted from some of the numerous volcanoes which stud the entire range. The Brazilian Andes, on the other hand, occupy a great breadth of country, but seldom exceed an elevation of 6000 feet.

The *geology* of the continent, so far as can be ascertained by a number of observations at distant and detached points, seems to present every formation—from the granites and primary schists, to the most recent alluvium and volcanic scories. In all the mountainous

regions primary rocks prevail, broken through by secondary traps, and capped by recent lavas. In the lower grounds, secondary rocks, up to the coal-measures and the chalk, have been detected; while the pampas and low plains, as proved by the researches of Mr Darwin, are of true tertiary and post-tertiary origin, of comparatively recent elevation, and replete with the remains of the megatherium, megalonyx; toxodon, and other creatures allied to the elephant, rhinoceros, tapir, llama, &c. but of more gigantic proportions and stranger configuration. (See GEOLOGY, No. 2, Vol. I.)

The *mineral* wealth of South America, though not perhaps the El-Dorado which our forefathers imagined, is unexcelled by any other continent. Gold is found abundantly in New Grenada, Brazil, Chili, Peru, and Bolivia; silver in Peru, Bolivia, Chili, and La Plata; tin and quicksilver in Peru; copper, lead, iron, &c. in various districts; coal in Chili and Panama; salt in Grenada and La Plata; nitrate of soda also in La Plata; diamonds in Brazil; emeralds, amethysts, and other precious stones in all the higher regions.

#### HYDROGRAPHY, &c.

The *islands, capes, straits, gulfs, &c.* connected with the surrounding seas of the continent present no very remarkable features. The chief islands are—the alluvial flats in the estuary of the Amazon; the Falkland and Georgian groups on the south-east, belonging to Britain; the desolate and rugged clusters of Terra del Fuego and Patagonia; the memorable islet of Juan Fernandez, off the coast of Chili; and the equatorial group of the Gallapagos in the Pacific. The more prominent capes are St Elena and Blanco on the west, Cape Horn on the south, and Frio and St Roque on the east. The principal strait is that of Magellan, about 300 miles long, with a breadth varying from 1½ to 40.

The *rivers* of South America are only excelled in magnitude and number by those of the northern portion of the hemisphere. The Amazon, the largest of rivers, spreads its hundred giant arms over a basin of more than 2,000,000 square miles in extent. It has a course of 4000 miles, and, with its branches, affords a boat-navigation of not less than 50,000. The La Plata has a course of 2400, receives the important affluents Parana, Pilcomayo, and Salado, has a basin of 1,200,000 square miles, the waters of which afford a navigation of 20,000 miles. The Orinoco has a course of 1800 miles, drains a region of 400,000 square miles, affording, with its affluents, a navigation of 8000. Indeed many of the tributaries of these giant rivers are larger than the largest of European rivers. The other independent rivers deserving of notice are the Magdalena, Tocantina, Parnaiba, San Francisco, Uruguay, and Colorado. As already stated, there are several fresh-water lakes situated in the high table-land of Bolivia and Peru—the largest of which is Titicaca, at an altitude of 12,700 feet, about 240 miles in circuit, and covering an area of 5400 square miles. The salt-lakes of La Plata are also of considerable size, but so shallow, that many of them are annually dried up, leaving saline incrustations of common salt, nitrate of soda, and the like, which are of considerable economical importance.

#### CLIMATE—BOTANY—ZOOLOGY.

The *climate* is thus described by Malte Brun:— 'The three zones of temperature which originate in America, from the enormous difference of level between the various regions, cannot by any means be compared with the zones which result from a difference of latitude. The agreeable, the salutary vicissitudes of the seasons, are wanting in those regions that are here distinguished by the denominations of frigid, temperate, hot, or torrid. In the frigid zone, it is not the intensity, but the continuance of the cold, the absence of all vivid heat, and the constant humidity of a foggy atmosphere, that arrest the growth of the great vegetable productions, and in man perpetuate those diseases that arise from checked perspiration. The hot zone of these places does not experience excessive heat, but it

## SOUTH AMERICA.

is a continuance of the heat, together with exhalations from a marshy soil, and the miasmata of an immense mass of vegetable putrefaction, added to the effects of an extreme humidity, that produces fevers of a more or less destructive nature, and spreads through the whole animal and vegetable world the agitation of an exuberant but deranged vital principle. The temperate zone, by possessing only a moderate and constant warmth, like that of a hothouse, excludes from its limits both the animals and vegetables that delight in the extremes of heat and cold, and produces its own peculiar plants, which can neither grow above its limits nor descend below them. Its temperature, which does not brace the constitution of its constant inhabitants, acts like spring on the diseases of the hot regions, and like summer on those of the frigid zone. Accordingly, a mere journey from the summit of the Andes to the level of the sea, or *vice versa*, proves an important medical agent, which is sufficient to produce the most astonishing changes in the human body. But living constantly in either one or the other of these zones must enervate both the body and the mind by its monotonous tranquillity. The summer, the spring, and the winter are here seated on three distinct thrones, which they never quit, and are constantly surrounded by the attributes of their power.

Of the vegetable productions more especially characteristic of the continent, we may mention the following—referring to the West Indies and the southern parts of North America (No. 69) for the more general and common forms:—The forests of Brazil and other tropical parts present the most luxuriant vegetation of palms, and tree-ferns tangled with rope-vines and other climbers, and studded with the strangest forms of the orchidaceæ. Here also flourish the mahogany and other timber-trees; the dye-woods of commerce; the banana, anana, cocoa, chocolate; the chincona, or Peruvian bark; the native potato; the caoutchouc-tree, Brazil-nut, castor-bean, pine-apple, agavé, and cactuses of innumerable species; while the rivers are covered with gorgeous floaters, among which is the celebrated *Victoria Regia* of Schomburgk. In the high grounds of Peru and Bolivia, the araucaria, the milk-tree, and gigantic courbaril, are met with; in Paraguay, the maté, or Paraguay tea-tree; La Plata is noted for its extensive thistleries; under the tropics are cultivated coffee, sugar-cane, cocoa, chocolate, tapioca, indigo, tobacco, cotton, and a thousand luscious fruits; while in Chili, 'the Italy of South America,' are grown the vine, olive, and ordinary European grains.

The animals deserving of notice are the wild horses and oxen of the pampas (none of which existed till introduced by Europeans); the llama or alpaca of the Andes; the tapir, jaguar, and tiger-cat; ant-eater, sloth, monkeys; the crocodile, guana, boa-constrictor, tree-frog, and other reptiles; the condor, rhea, albatross, and innumerable sea-fowl, whose droppings on the rainless islets of Peru constitute the *guano* of commerce; the electric eel, Silurus, and other curious fishes; the cochineal insect, gigantic spiders, centipedes, luminous flies, and other insect forms unknown to the old world.

### POPULATION—GOVERNMENTS.

The population of South America is small compared with its extent and fertility, the general estimate being 14,517,000—of which 1,100,000 may be whites, 4,000,000 Indians, 3,050,000 blacks, and the remainder mixed races. The whites are chiefly of Spanish origin, except in Brazil, which was settled by the Portuguese; in Guiana, where there are a number of English, French, and Dutch; and in the city and district of Buenos Ayres, where there are also a few English and French. The Indians, once the sole possessors of the continent, were subdued in the early part of the sixteenth century by the Spaniards and Portuguese; but they still retain their independence in Patagonia and on the upper waters of the Amazon. They belonged chiefly to four families of the American variety—namely, the civilized Toltecan of Bogota, Peru, and Chili; the rude

and robust Brazilians, occupying the eastern section of the continent from the Orinoco to the La Plata; the gigantic and brave Patagonians; and the miserable Fuegians. The religion of the aborigines was, as it is for the most part still, idolatrous; the Roman Catholic ritual prevails in the states originally settled by the Spaniards, Portuguese, and French; and Protestantism in British and Dutch Guiana.

From their original establishment till the beginning of the present century, all the South American states were subject to European nations; but during the troubles in Spain and Portugal, their colonies threw off the yoke, and became independent. Since their independence, the Spanish provinces, after much contention and division, have formed themselves into the *republics* of Venezuela, New Grenada, Ecuador, Peru, Bolivia, Chili, La Plata, Paraguay, and Uruguay. Brazil is a limited monarchy, under a sovereign styled emperor; and the only colonies are the small ones of British, Dutch, and French Guiana, to which may be added the Falkland Islands, now governed and protected as a British dependency. The following table exhibits the names, extent, population, and chief towns of the different states, including Patagonia, which is not yet claimed by any civilized power:—

States.	Sq. Miles.	Population.	Chief Towns.
Venezuela, -	400,000	1,000,000	Caracas.
New Grenada, -	425,000	1,600,000	Santa-Fé-de-Bogota.
Ecuador, -	200,000	680,000	Quito.
Peru, - - -	480,000	1,500,000	Lima.
Bolivia, - - -	440,000	1,400,000	Chiquisaca.
Chili, - - -	155,000	1,180,000	Santiago.
La Plata, - - -	890,000	1,700,000	Buenos Ayres.
Paraguay, - -	80,000	240,000	Assumption.
Uruguay, - - -	68,000	90,000	Monte Video.
Brazil, - - -	3,192,000	4,800,000	Rio Janeiro.
B. Guiana, - -	67,000	100,000	Georgetown.
D. Guiana, - -	36,000	78,000	Paramaribo.
F. Guiana, - -	27,000	22,000	Cayenne.
Patagonia, - -	340,000	110,000	....
Falkland Isles,	135,000	17,000	Port Louis.
Total, - - -	6,935,000	14,517,000	

Such are the existing political divisions, which we shall now describe in detail, remarking once for all that the industrial pursuits of the people are as yet chiefly limited to the raising and collecting of raw produce for shipment to Europe, from which most of the manufactured articles are received in exchange.

### VENEZUELA.

On the death of the celebrated Bolivar in 1830, Venezuela, New Grenada, and Ecuador—the three component states of the old Spanish territory of Colombia—peaceably agreed to become independent of one another. The limits of these states are nearly the same as they were when each was a separate province subject to Spain. Their constitutions are based on the most liberal republican principles, and they are leagued together for mutual support against foreign aggression. The national debt of Colombia was equally divided amongst the three states in December 1834; slavery was abolished; and, upon the whole, they are likely to go on much more peaceably and rationally apart, than if they were united under one head.

Venezuela extends from the republic of Ecuador to 12° of north latitude, and from 60° to 71° west longitude. On the north and east it is washed by the Atlantic Ocean, and has a number of available ports. The most remarkable feature of the country is the great river Orinoco. It is also traversed by the Andes; and the great lakes of Maracaybo and Valencia belong to its territory. The northern part is mountainous; but in the south, on the banks of the Orinoco, are those immense plains or *llanos*, the climate of which is hot, and in some parts unhealthy. The year is completely divided into the rainy and the dry seasons; the former commencing in November, and ending in April. The

productions are sugar, coffee, indigo, cotton, and tobacco. The plains on the Orinoco furnish extensive pastures, which support numerous herds of cattle. Venezuela is partitioned into four departments, and further divided into twelve provinces, which contain in all a population of nearly 1,000,000. The annual budget is somewhat under 2,000,000 piastres; and according to the division of the national debt already noticed, £1,941,795 fell to the share of Venezuela. The patronage of the church has been taken from the archbishop of Caracas, and is now in the hands of the president. Tithes are abolished, the clergy being paid by the state. Monastic institutions and missions have been done away with, their income and possessions being applied to the uses of the National College established at Maracaybo for public instruction. The principal towns of Venezuela are Caracas, with a population of probably 40,000; Cumana, a sea-port, with 25,000 inhabitants; Varinas, with 12,000; and Maracaybo, situated on the margin of the great lake of the same name, which has 25,000 inhabitants. The cultivation of the soil and the rearing of cattle are the great objects of industry in this republic. The chief articles of export are cocoa, coffee, sugar, tobacco, hides, dye-woods, sarsaparilla, Peruvian bark, balsam, indigo, furs, &c. The imports are for the most part the fabrics of England and France. It is difficult to state with certainty what the exports and imports may amount to respectively, but the former may be estimated at 2,000,000, and the latter at 4,000,000 of piastres. (A piastre is equal to 4s. 3½d. sterling.)

NEW GRENADA.

This republic is bounded on the north by the Caribbean Sea and Guatemala; on the east by Venezuela and Guiana; on the south by the Amazon and Ecuador; and on the west by the Pacific Ocean. The great chain of the Andes traverses this country, and the mountains are extremely rich in gold and silver; and there are also mines of platina, copper, lead, and emeralds. The value of gold and silver produced annually is stated at £650,000. It is divided into five districts and thirteen provinces, the united population of which exceeds 1,600,000. Santa-Fe-de-Bogota is the capital of the republic; it has a population of about 40,000. Here a national academy was opened in 1833. In 1835 the income amounted to 2,337,836 dollars, and the expenditure to 2,211,554 dollars, leaving a balance of 126,282 dollars for payment of the interest of the national debt—the share falling to New Grenada being above £3,000,000. The principal articles of export are cocoa, indigo, tobacco, coffee, hides, and cattle. The imports are manufactured goods of almost every description. What the value of these may be it is impossible to say, for the contraband trade has been carried on in the country to an almost unparalleled extent.

ECUADOR.

The territory of the Equator comprehends the ancient presidency of Quito. On the south it borders on Peru and Brazil, the latter country forming also its eastern boundary; on the north its limits are New Grenada; and it is washed by the Pacific Ocean on the west. This republic is intersected by both chains of the Andes, and consequently presents great diversity of surface and climate. The high valleys enjoy a temperate climate, although situated immediately under the equator, a consequence of their great elevation. They are extremely fruitful, and would be the most charming places in the world, were it not for the destructive earthquakes and volcanic eruptions with which they are not infrequently visited. There are sixteen active volcanoes in Quito; and some of the most frightful earthquakes on record have taken place in this country. The valley in which the city of Quito is situated is allowed to be the finest table-land in America, and all travellers speak in glowing terms of its surpassing loveliness. Gold and silver are comprised in the metallic riches of the mountain territory. The re-

public is divided into eight provinces, the population of which is estimated at 680,000, more than the half of whom are Indians, who dwell in the mountains. The capital of the country is Quito, one of the largest and finest cities in the new world. It stands at an elevation of 9000 feet above the ocean level, but being nearly under the equator, has a bland and genial climate. Quito has two universities, and it has always enjoyed celebrity for the great number of students by which they are attended. The population is estimated at 75,000. The great port of this republic, and indeed of the whole three republics formerly constituting Colombia, is Guayaquil—the exports and imports from which respectively average about £250,000 annually. The imports consist chiefly of British manufactures, flour, wine, and other necessaries; the exports of cocoa, timber, and the various other vegetable products of the country. With regard to the income and expenditure, little correct information is to be obtained. By the treaty regarding the national debt, £1,464,795 fell to the lot of the republic of Ecuador.

PERU.

Ever since the declaration of independence, Peru has been a scene of political squabbling and change, into the details of which we need not enter. At present, the republican state known as Peru is bounded on the north by Ecuador, on the east by Brazil, on the south by Bolivia, and on the west by the Pacific Ocean. Its length is computed at 1500 miles, but its coast-line cannot be less than 2100, reckoning the bendings of the shore. According to Humboldt's estimate, Peru comprises an area of 480,000 square miles. The surface of this vast territory is of the boldest and most varied description. It is naturally divided into three regions—Western Peru, situated to the west of the Andes; Eastern Peru, situated to the east of that mountain chain; and Perz of the Andes, which comprises the mountainous districts. Western Peru is a belt or zone of sand nearly 2000 miles in length, and having an average breadth of thirty or forty miles. No rain falls throughout the whole of this desolate Sahara of the west, and vegetation only springs up on the banks of the rivers which run from the Andes to the Pacific. The habitable parts of Western Peru, therefore, are merely a series of oases 'islanded amid the waste of sand,' like those of Africa. Yet here are situated the city of Lima and several other large towns, the only seaports of the republic. Peru of the Andes, as might be inferred from its varied elevation above the level of the sea, presents a great diversity of soil, climate, and vegetation. Suffice it to say, that in different parts it exhibits every species of production, from the dwarf plants of Lapland which clothe the lofty mountain tops, to the aromatic species of Sumatra, which shed their odours at its base. This portion of Peru contains the sources of those vast rivers which traverse the whole continent of South America, and are the greatest on the face of the globe. But by far the largest, most beautiful, and most valuable part of the Peruvian territory lies to the east of the Andes, commencing on the eastern declivity of the second chain, and stretching to the confines of Brazil. In this vast region a thousand sources of wealth lie buried, for the greater part of it may be said to be yet unknown, although the riches which it contains are immense. In fertility, luxuriance, and variety of vegetation it rivals Brazil, and the world does not present us with any higher standard of comparison. Every sort of production which springs from the ground may be raised in one part of Peru or another in the amplest abundance. Its mineral treasures are gold, silver, platina, tin, copper, lead, quicksilver, precious stones, salt, alum, saltpetre, coal, sulphur, and others. The most valuable of these are in great plenty.

Peru carries on considerable trade with Great Britain, the United States, France, the kindred republics of South America, and other places. A treaty of amity, commerce, and navigation with Great Britain

## SOUTH AMERICA.

was signed at Lima on the 5th of June 1837, by which perpetual freedom of trade was established with the countries of the Peruvio-Bolivian confederation. The chief articles of export are gold and silver, Peruvian bark, hides, nitre, sugar (unrefined), cotton, and sheeps' wool, tin, molasses, pot and pearl ashes, &c. The imports into Peru from Great Britain, chiefly of manufactured goods, amounted in 1846 to £820,535; and the exports, chiefly to Britain and the United States, to more than £1,800,000. The present revenue of Peru has been estimated at £1,250,000; the expenditure at a little less than that sum; and the national debt at £6,000,000. But precise information on these points is not to be obtained. The religion of the republic is the Roman Catholic, no other being tolerated. Slavery has been long abolished here; but the state of the country in regard to education and morals is still very low. The total population of Peru is estimated at 1,500,000, consisting of three original castes—Spaniards, Indians, and Negroes, and all their possible combinations. Lima, the capital, which was formerly the grand entrepôt for the trade of all the west coast of South America, contains a population of 70,000. All the trade is carried on at Callao, which, although six miles distant, is the port of Lima. The next most important place is Cuzco, the chief town of the interior, and the ancient capital of the incas. Here are some magnificent remains of the former riches and splendour of Peru, particularly a Temple of the Sun, the wealth of which, when first spoiled by the Spaniards, was almost incalculable. The remembrance of the ancient heathen worship is still preserved by a honorary institution called the 'Order of the Sun.' Besides Lima and Cuzco, the next largest town is the maritime port of Arequipa, which has been six times destroyed by eruptions from a neighbouring mountain, and yet possessed a population of 40,000 previous to the revolution. Earthquakes are frequent in Peru. The city of Lima has been three times almost entirely destroyed by these frightful visitations—namely, in 1687, 1746, and 1828.

### BOLIVIA.

After independence was established in 1825, this portion of the ancient viceroyalty of Buenos Ayres received the name which it now bears, conferred in honour of the liberator, General Bolivar. It is bounded on the north by Peru and Brazil, on the east by Brazil, on the south by the Buenos Ayrean provinces and Chili, and on the west by the Pacific Ocean and Peru. It comprehends a space of 480,000 square miles, and the population is estimated at 1,400,000, of whom probably two-thirds are Indians. This republic includes the departments of Potosi, Chuquisaca, La Paz, Santa Cruz, Cochabamba, and Oruro. The greater part of Bolivia is situated at a very high elevation, but towards the east it stretches down in extensive plains towards Brazil. The climate, therefore, is extremely various. On the high parts, snow-storms and hurricanes frequently prevail, and the plains, from the rigour of the weather, are nearly destitute of vegetation. The climate of Potosi, at an average elevation of 13,400 feet, is so changeable, that it frequently exhibits in one day all the vicissitudes of the four seasons of the year. Thence descending through the regions of Oruro, at an elevation of 12,400 feet, La Paz at 12,100, Chuquisaca at 9300, Cochabamba at 8400, down to the plains of Majos and Chiquitos, all the known degrees of temperature, from extreme cold to extreme heat, are experienced. This elevated region is enriched with the most valuable mines of gold and silver, which, with other precious metals, form the only articles of Bolivian commerce. The mountain of Illimani in La Paz, which is supposed to contain rich veins of gold ore, is 24,200 feet above the level of the sea. From the great difficulty of working the mines, and the expense of extracting the ore, the greater part of the gold of Bolivia is obtained from the *lavaderos*, or gold washings in the beds of rivulets, where it is found in the shape of grains. Silver, how-

ever, is the great staple metallic production of Bolivia; and the famous mountain of Potosi is ranked next in importance to the mines of Guanaxuata in Mexico.

On account of the inconsiderable nature of the rivers flowing from Bolivia to the Pacific, and the badness of the roads, it is impossible this country can enjoy much commerce with the Pacific; but towards the east, several large streams communicate with the great navigable rivers that flow into the Atlantic Ocean. The river Paro, or Beni, which rises near La Paz, and the Guapey, which rises near Cochabamba, after a long sweep, unite with the Mamori, and, flowing to the north-east, mingle with the waters of the Marañon or Amazon. The Pilcomayo, again, which rises near Potosi and Chuquisaca, and the Vermejo, which rises in the valley of Tareja, flow to the south-east, and mingle with the Paraguay, the upper part of the mighty Rio de la Plata. All these rivers are navigable almost to their source, and, with steam navigation, would open up a direct communication between these wealthy districts and the nations of Europe. The table-land of Titicaca is the most elevated on the globe, with the exception of that of Thibet; but while the latter only presents pastures and flocks of sheep, the former exhibits towns and populous cities, and is covered with fine crops of wheat, barley, rye, &c.

### CHILI.

Chili is bounded on the north by La Plata, on the east and south by Patagonia, from which it is separated by the Andes, and on the west by the Pacific Ocean, along the shores of which it stretches from 21° to 43° of south latitude. It is 1300 miles long, and from 30 to 120 broad. The ground ascends gradually from the ocean to the Andes, but is intersected by their projecting branches, some of which run almost down to the sea-shore. There is no deficiency of rivers in Chili, but in general they are small, and running from the Cordillera to the Pacific, they have necessarily short courses. These streams are indispensable to the existence of agriculture, in a country where it rains very seldom, and to a very limited extent. The fertility of the soil of Chili has in many respects been much overrated. It presents great diversities. In some parts where irrigation is deficient, it is barren and unproductive; in others quite the reverse; and amid splendid woodlands, the finest crops of wheat, barley, rye, and other species of grain are raised, with scarcely any trouble to the cultivator beyond scattering the seed. Cotton, sugar-cane, vines, &c. are also extensively cultivated. The country is perfectly free of all noxious reptiles, the climate salubrious, and the weather serene. The want of navigable rivers is unfavourable to commerce; and although there are many rich mines of gold, silver, and copper in the northern provinces, the sterility of the country around them prevents many of them from being worked to advantage.

In 1827, the directorship of Chili was changed into a presidency, in imitation of the United States. The established religion is the Roman Catholic, the priesthood not being numerous, as was the case prior to the revolution. The constitution of Chili is that of a federal republic, consisting of three states—namely, Coquimbo, Santiago, and Concepcion, and one district, Chiloe, each having a provincial assembly, and all four a common congress, or executive power, which holds its sittings at Santiago. Chili is divided into eight provinces, which contain a population of about 1,180,000. The principal towns are Santiago, with 65,675 inhabitants; Valparaiso, with 26,000; and Concepcion, with 10,500. In 1840, the outlay of the state was reckoned at 2,000,000 dollars, the receipts being about 400,000 dollars more, which served to pay the interest of the English loan, or at all events a part of it; for their affairs are in great confusion, and their debts are so mixed up with those of Peru, that it is difficult to determine how they stand. By allowing the interest of their loan to remain for years unpaid, the debt has accumulated in such a manner as to have destroyed

national credit. The perpetual broils with Peru have materially contributed to retard the advancement of this country, which has certainly very considerable resources, and an enterprising and intelligent population. During the year 1840, there was exported from Chili gold, silver, and copper to the amount of 3,500,000 dollars. The other chief articles of export are hides, timber, wheat, flour, fruits, Peruvian bark, indigo, tin, and seal-skins. The imports into Chili from Great Britain, chiefly of manufactured goods, amounted in 1846 to £959,322. The native manufactures of Chili are insignificant. Valparaiso is the great port of Chili into which all foreign goods enter—between 400 and 500 vessels there annually discharging their cargoes.

#### • LA PLATA.

The united provinces of La Plata, or the Argentine Republic, comprises the whole of that vast space extending from the cordillera of Chili and Peru to Brazil, with the exception of Paraguay and the Banda Oriental, which are independent states. It comprises an area of 890,000 square miles, and is divided into thirteen provinces, which to a certain extent govern themselves independently of each other, but for all general or national purposes are confederated by conventional agreements. For want of a more defined national executive, the provincial government of Buenos Ayres is temporarily charged with carrying on the business of the union with foreign powers, and with the management of all matters appertaining to the republic in common. The executive power of that government, as constituted in 1821, is vested in the governor or captain-general, as he is styled, aided by a council of ministers appointed by himself, responsible to the junta, or legislative assembly of the province by which he is elected. The junta itself consists of forty-four deputies, one-half of whom are annually renewed by popular election. It was at first attempted to establish a system of federalism, by which Buenos Ayres should exercise immediate control over the other provinces; but from various causes the plan proved quite abortive. The national organisation of this state is now limited to the slender bonds of voluntary confederation, not only with each other, but with the old metropolis, Buenos Ayres. The whole territory is an almost uniformly level plain of great fertility, watered by the large rivers La Plata, Parana, Paraguay, and Uruguay, and several others of smaller dimensions; the Salado, Pilcomayo, Vermejo, and Nuevo, being the most important. There are likewise a number of lakes, the waters of which are brackish. There are almost no natural trees in the province, but there are numerous plantations, or rather orchards, of peach-trees, which the natives cultivate for firewood—the fruit being applied to feeding the swine and poultry. Deer are plentiful in the wilder parts, but little prized where there is so much fine beef. The climate is extremely salubrious, and, singularly enough, is almost entirely governed by the winds, which, generally speaking, are northerly.

One of the distinguishing characteristics of La Plata are the vast plains called *pampas*, one portion of which extends from the banks of the Paraguay westward to the frontiers of Los Charcas, and northward to the mountains of Chiquitos—another immense plain, 300 miles in length from east to west, and 1500 miles from north to south, as far as Patagonia. These plains present one uniform expanse of waving grass, uninterrupted by either wood or eminence, although in some places parched and barren, and perfectly uninhabited, unless by innumerable herds of wild oxen, horses, ostriches, and other animals. Over these pampas lies the only route by land from Buenos Ayres to Chili, which journey was formerly performed by large companies, as the plains were infested by hordes of roving Indians, who went there to hunt, catch wild horses, and plunder. From the absence of all permanent landmarks, the travellers over these immense plains shaped their course by the compass, and their caravans were in reality moveable houses, solid and defensible. Of

late years, regular post-houses have been established along the whole line of road betwixt Santiago (the capital of Chili) and Buenos Ayres—a distance of nearly 1400 miles—and a regular communication is kept up betwixt the two republics by means of couriers, who perform their journeys with uncommon speed.

The city of Buenos Ayres is situated on the southern margin of the river Plata, where the latter is formed by the confluence of the Parana, Uruguay, and Negro rivers. It is thus, as it were, the key to all the internal navigation. The city occupies a large extent of ground, being about 2 miles long, and  $1\frac{1}{2}$  broad, all the streets crossing at right angles. There are a university, several educational establishments, and a number of churches. The prosperity of Buenos Ayres and the other provinces is greatly impeded by the defective navigation of the river Plata, which is filled with shoals and sandbanks, and therefore dangerous to large vessels; otherwise the city of Buenos Ayres would become one of the largest emporiums of commerce in the world. The Parana and Uruguay are navigable for vessels of from 200 to 300 tons 1500 miles into the interior; the former running through Paraguay into the centre of Bolivia.

The estimated population of the provinces of La Plata is 1,700,000, inclusive of independent Indians within the territory laid claim to by the republic. Of this number of inhabitants, from 180,000 to 200,000 were reckoned as belonging to Buenos Ayres. Into details of trade we cannot enter; indeed it is impossible to obtain correct information regarding the interior provinces, their commerce being mostly of a domestic or internal nature. Buenos Ayres is of course the great centre of foreign trade. In 1845, the imports from Great Britain amounted to £592,279; the total imports into the republic being valued at 7,000,000 dollars. The exports during the same year amounted to 6,100,000 dollars, consisting chiefly of ox hides, gold and silver, sheeps' wool, jerked beef, horse hair, tallow, sheep-skins, and other products of the country. Of late years, the imports into Buenos Ayres have decreased, in consequence of internal feuds and revolutions, whilst those of Monte Video have increased.

#### PARAGUAY.

The republic of Paraguay, formerly one of the united provinces of the viceroyalty of Buenos Ayres, is situated between the rivers Parana (on the east and south) and Paraguay (on the west). It is divided by a desert tract from Brazil on the north. It comprises an area of about 80,000 square miles, with a population of about 240,000, seven-tenths of which are Creoles. The climate is mild and healthy, although moist, being low and level. All sorts of tropical fruits, corn, vines, sugar-cane, rice, maize, tobacco, indigo, and a number of valuable medicinal plants, abound in profusion. There is a particular plant peculiar to Paraguay called *yerba*, and when decocted, *mate*, which greatly resembles the tea of China, and is by many preferred to the latter. It is universally used in South America. Of late years it has been cultivated in Brazil with great success. Immense herds of cattle roam over the plains, whose hides and tallow form an article of commerce.

From shortly after the declaration of independence in 1811, until 1838, this beautiful and prolific region was governed in a despotic manner by Doctor Francia, a man of considerable talent, but it is believed partly crazed in mind, who had the address, like Cromwell, to dissolve the temporary government established by the revolutionary party, and to appoint himself sole and perpetual dictator of the state. All things were now managed by him; he planned roads, bridges, and other public works, organized the army, and interfered in the most minute arrangements. His rule was supported by excessive cruelty, and he lived in constant fear of assassination. This extraordinary despot died, in his eighty-second year, in 1838; but what has been the political condition of the state since we have not heard. Some writers are disposed to think that upon the whole Francia's dictatorship was beneficial for the country,

as he carried on various objects of utility, and procured respect and tranquillity for his people.

## URUGUAY, OR BANDA ORIENTAL.

This comparatively small state, which occasioned a long and bloody contention between the united provinces and the Brazilian government, is situated between the river Uruguay and the Atlantic from south to north, and between the rivers Plata and Parana from east to west, occupying an area of about 68,000 square miles. From its position, between the Spanish and Portuguese settlements, it soon became an object of contention; but it would be a waste of time to follow the course of the struggle. Suffice it to say, that after much blood had been shed on both sides, in a war of more than half a century's duration, during which the disputed territory, by being the common battle-field, was devastated by both, the contending parties at last drew stakes, and it was erected into an independent state in 1829. It is equally distinguished for fertility of soil, salubrity of climate, natural beauty, and geographical position. It abounds in excellent pastures, which are fertilised by an unusually large number of streams, in which respect it is greatly superior to the rival provinces on the opposite banks of the Rio de la Plata. The city of Monte Video, the capital of the republic, is situated on the northern bank of the great river just named, near its mouth, 120 miles north-east from Buenos Ayres. The importance of this city has greatly increased since the erection of the country into an independent republic. A lowering of the duties on import trade, whilst those of Buenos Ayres remained high, brought foreign goods to it, so that it has in some measure supplanted its rival, and become an entrepôt for the supply of the neighbouring provinces. This is the cause of the diminution in the amount of imports into Buenos Ayres, to which allusion has already been made. In 1836, the importations of foreign goods into Monte Video amounted to £659,530, whilst the exports were nearly equal in value, and now constitute an important proportion of the returns in the general account of the trade with the river Plata. The population of the Banda Oriental is estimated at from 90,000 to 100,000, and is rapidly increasing.

## BRAZIL.

Brazil is by far the largest and most important state in the New World. The climate is more generally salubrious and agreeable than that of any other tropical country, and every part of the soil is rich, fertile, and exuberant of vegetation. It is bounded on the land side by Banda Oriental, Paraguay, Bolivia, Peru, Colombia, and Guiana; and on the east and north-east by the Atlantic. The territory within these limits has been estimated at 3,192,000 square miles; the population, inclusive of Indians, at 4,800,000.

Brazil was governed in much the same way as the Spanish colonies until the year 1808, when King Joam VI. fled from Portugal to escape the power of Bonaparte, who had taken a fancy to his dominions. He was warmly received by the Brazilians; nor was their joy misplaced, for he immediately set about freeing the territory from all the marks of colonial dependence. The press was made free, newspapers established, and the ports thrown open to traders of every nation, and everything done to promote education and industry. In 1815 also Brazil was created an independent state, although annexed to the crown of Portugal. In 1817, some democratic insurrections broke out in Pernambuco; and although suppressed, discontent still continued, until, in 1821, it was announced that the Portuguese constitution was to be conferred on Brazil. Before this, however, King Joam had sailed for Portugal, promising at his departure increased pay to all his officers and soldiers. But when he was gone, it was found he had carried off every farthing that was in the treasury, having also raised immense sums by means of treasury bills. The public indignation at this discovery, together with the suspicion that he intended again to

reduce Brazil to the condition of a vicerealty, occasioned a general call for his son Don Pedro, who had been left as regent, to become the head of the government as an independent state. This he readily complied with. In 1822 he was proclaimed emperor; and in 1825 his title and the independence of Brazil were acknowledged by his father. In 1831, owing to his unpopular and despotic measures, Pedro was compelled to abdicate in favour of his son Pedro II., under whom Brazil enjoys the name, but unfortunately not the peace and security of a constitutional government.

The form of government is that of a constitutional and representative monarchy, the imperial crown being hereditary in the male line. Four political powers are recognised—the legislative, which resides in a general assembly, consisting of a senate, appointed by the emperor, and a chamber of deputies elected by the people; the executive, the managing, and the judicial, are the other three powers. In 1835, it was decreed that a legislative provincial assembly should be introduced into each of the nineteen provinces, the duration of each session to be two years. The local powers of these bodies are very considerable, approaching to those of the individual states of the North American Union. The religion of the state is the Roman Catholic, but the exercise of all others is permitted, though none are allowed to build churches or perform divine service in public. There are a great number of monasteries and nunneries in Brazil, and the clergy is numerous. Much has been done for public instruction in Brazil, a national system of education having been introduced. The press is free, but as yet there are few printing establishments in the country. Nothing is wanting but internal tranquillity to enable the Brazilians to make advances in literature and the useful arts.

To describe minutely the physical characteristics of so vast a region as that of Brazil, would carry us far beyond our limits. Generally speaking, there is not on the globe a finer country, one blessed with a more genial climate, or a more fertile soil; more happily diversified with wood and water, or with abundance of navigable rivers; or more famed for its produce of gold and diamonds. Nearly the whole of the most highly-valued productions of the earth are raised within its territory. The land rises by gentle gradations from the shore to the interior, to the height of from 3000 to 6000 feet above the level of the sea. At this elevation within the tropics the climate is temperate, and European fruits and grains are raised in abundance. The intervening valleys have a warmer temperature, and consequently are extremely favourable to the growth of sugar, coffee, cotton, and every description of tropical produce. Magnificent forests overspread a great part of the interior. The trees are closely interwoven with brushwood and shrubs, and covered with creeping plants adorned with the most resplendent flowers, thus imparting a peculiar and rich appearance to the scenery. These forests abound in valuable woods, adapted for every purpose to which art can apply them. The climate in the neighbourhood of the Amazon, and in the northern parts, is hot, but ameliorated by the humidity of the atmosphere; in the southern regions it is temperate, and in general healthy.

Brazil is rich in mineral treasures, especially in gold and diamonds. Gold is found in the beds of most of the rivers that rise in the interior, and almost all the towns were founded by men searching for gold. Next to gold, diamonds form the staple of Brazilian mineral riches. They were first accidentally discovered about 1730. There are several large mines of nitre and iron, but no silver is found. Salt is extremely abundant, but being a government monopoly, it is always kept very high in price; a most absurd regulation in a country where it is so much required, not only for the use of man, but of cattle, poultry, sheep, and other animals, and for salting meat. The commerce of Brazil is very extensive, especially with Great Britain. Though labouring under the curse of being a slave-holding state—a condition of things incompatible with sound insti-

tutions—Brazil is yearly improving in circumstances, and exhibits very satisfactory symptoms of commercial prosperity. All that it requires, exteriorly, is liberty to trade on equitable terms with Great Britain, where its vast produce of coffee and sugar would find a market. At present it raises 60,000 tons of coffee annually, and this could be greatly increased. Brazil is well known as being the best South American customer of Britain, particularly for cotton goods. At present its imports from the United Kingdom amount to about £4,000,000 annually, and between 50,000 and 60,000 tons of British shipping are engaged in the trade, chiefly in connection with Liverpool. The imports into Brazil from the United States during the year 1835 amounted to 2,608,656 dollars, being chiefly flour; from France, to the extent of £907,330. The whole imports into Brazil may be estimated at £6,500,000. The exports, consisting of sugar, cotton, hides, coffee, tobacco, rice, leather, drugs, dye-woods, India-rubber, gold, diamonds, are estimated at £5,500,000, of which about £1,500,000 comes to Great Britain. According to the report of the finance minister, the income for the year 1838 was 13,663,289 dollars, the expenditure 13,622,000 dollars, leaving a balance of 41,289 dollars. There is a yearly increasing debt of above £6,600,000.

The capital city of Brazil is Rio Janeiro, of which the population is estimated at nearly 200,000. The harbour is one of the finest in the world. The entrance to it is a narrow opening in a ledge of rocks, about half a mile wide, at the mouth of which is an island, upon which a strong fort is erected. After passing through this strait, the mariner finds himself in a magnificent gulf 100 miles in compass, encircled by lofty mountains, and enclosing a number of islands. Vessels of all dimensions may enter and anchor in perfect security. The city is on the north-east side of the bay; the streets in one part are narrow, and the whole appearance of the lower city is somewhat mean. It is, however, now greatly improved, by the erection of public and private buildings. The greatest portion of the mercantile inhabitants are Portuguese. One of the most striking features of Rio is the immense number of churches with which it is provided. Bahia, or St Salvador, the ancient capital, is situated on the east side of the magnificent bay of All-Saints, which extends a whole degree from north to west, branching inland in every direction, and capable of holding all the shipping in the world. The population is estimated at 120,000, so that it is the second city in Brazil. From its central situation, the commerce is very extensive. Pernambuco is the next city in size and importance, and is increasing so rapidly, that new houses are built wherever space can be found, while the commerce is increasing in proportion. It is perhaps the handsomest city in Brazil, with broad paved streets, fine houses, an Episcopal palace, handsome churches, convents, hospitals, theatre, &c. The population is estimated at upwards of 62,000.

#### GUIANA.

This territory is divided into British, Dutch, and French Guiana. It is situated north of Brazil, between Cape North and Essequibo, inclusive. The portion claimed by Britain extends from the river Coventyn, in 56° 58', to Punta Barima, at the southern outlet of the Orinoco, in 60° 6' west longitude, in breadth, and from the Acaria mountains to the sea, in length. It formerly consisted of the settlements of Demerara, Essequibo, and Berbice, but these are now united under one government, and include 67,000 square miles. The whole coast is flat, and on approaching from the sea, nothing is visible but the tops of the trees, which seem to be growing out of the water. This alluvial flat extends from ten to forty miles inland, and is terminated by a range of sand-hills, which approach within two miles of the sea, on the south side of the Essequibo. Parallel with these sand-hills run several detached groups of hillocks, of moderate elevation. Farther into the interior the country is much divers-

fied with mountains and valleys. Immense savannas, or plains, occupying 14,400 square miles, extend between the rivers Demerara and Coventyn, approaching the sea at the river Berbice. These plains appear to have been an inland lake, and are sandy, growing only a few stunted trees; but they are very rich in pasturage. Guiana has three great rivers—the Essequibo, the Berbice, and the Demerara. The Essequibo, the largest of these rivers, is about 620 miles in length, but, from the number of rapids, it is only navigable for 50 miles from its mouth. During its course, it receives the waters of several large tributaries, which irrigate an immense tract of country. To the eastward, and running parallel to the Essequibo, is the Demerara, which is navigable for vessels of small size about 85 miles above Georgetown. The Berbice, although smaller than the Essequibo, is of more importance, from its course being free for vessels drawing twelve feet water about 105 miles, and for vessels of seven feet draught 165 miles into the interior of the country. The river Coventyn forms the boundary between the British and Dutch possessions, and is navigable 150 miles for vessels drawing seven feet of water. There are also several smaller streams in the intervals between these great rivers, which, although of no importance for navigation, are extremely useful in the irrigation of the country. This fertility is kept up during the dry season by heavy falls of dew; and this takes place not only on the banks of the rivers, but also in the open plains. The soil is very fertile, in some parts sandy, but growing abundance of grass, and in others it is a strong retentive loam, well adapted for the cultivation of coffee, sugar, rice, and other kinds of tropical produce. The coast is covered with mangrove and curina bushes; and towards the interior thick forests occur, which yield many valuable kinds of timber, drugs, and dye-stuffs.

British Guiana is divided into three counties, Demerara, Essequibo, and Berbice. The two former have been united, and are divided into eleven parishes, and the latter into six. These colonies were first settled by the Dutch, captured by the British in 1796, given up to the Batavian Republic in 1802, retaken in 1803, and finally ceded to this country at the general peace of 1814. The settlements are all situated upon the banks of the rivers from which they receive their name, extending along both sides, and generally as far inland as the rivers are navigable. Each plantation has a wharf or landing-place of its own, and canals are cut into the land for the admission of boats, and the draining of the surrounding country. For 50 miles along the sea-coast of the county of Berbice, a huge embankment has been raised against the sea, on which is a carriage-road 60 feet broad. A comparatively small portion of Guiana is yet cultivated, and an immense field for colonial industry still lies open. The extent of cultivated land, however, is gradually increasing as the advantages of the colony are becoming known. The staple products consist of sugar, rum, coffee, and cotton; and it is thought, from the fertility of the soil, and the constant summer which prevails, that many other valuable plants might be cultivated. The climate is very genial and regular throughout the year, the maximum heat being 90°, the minimum 74°, and the mean temperature about 82°. Two wet and two dry seasons constitute the changes of the year; the great wet season, as it is called, commencing in the middle, and continuing till the end of August, and the great dry season from the end of August till the end of November. The short wet season occurs from December to the middle of February, and the short dry season from February to April. The foregoing applies to the coast regions, the interior being marked by only two great changes during the year.

The population of Guiana may be divided into Europeans, Africans, people of colour from other parts, and native Americans. The native Americans have dwindled down to a very small number, who lead a wandering life on the frontiers and savannas of the colony. The government is vested in a governor and court of policy,

## WEST INDIA ISLANDS.

consisting of the governor, chief-justice, attorney-general, collector of customs, government secretary, and an equal number of persons elected from amongst the colonists. Formerly, all free male inhabitants were liable to serve in a military capacity, but since the abolition of slavery the militia has been disbanded. The local government have made the greatest efforts to promote education in the colony, and many schools and churches have been erected at considerable expense.

The capital of British Guiana is Georgetown, situated on the western bank of the river Demerara, which has a population of from 20,000 to 25,000. The streets are generally wide, traversed by canals; the houses built of wood, two storeys high, and separated from each other by gardens and ditches. It is built in two rows, about a mile long, on the river side, and contains several handsome buildings. New Amsterdam, the chief town in the county of Berbice, extends about a mile and a-half along the western bank of the river Berbice. The houses have all gardens behind, and are separated from each other by canals or trenches, and the town is described as presenting altogether a very pleasing aspect on entering the river. The population of this town, according to the last-published census, amounted to between 3000 and 3500.

The exports from Guiana, as is the case with all the other West India colonies, have decreased of late years; but from the encouragement which is now given to emigrants, it is hoped that this will in the course of time be remedied. The exports, consisting chiefly of sugar, molasses, rum, coffee, and cotton, amount from £1,500,000 to £2,000,000; and the imports, chiefly of British manufactures, to little short of £1,000,000.

The settlement of Cayenne, or *French Guiana*, was first formed about 1630 by a colony from Caen in Normandy, after which it is called. It did not succeed. From that period down to the peace of 1814, it passed alternately into the hands of the Dutch, British, Portuguese, and French, but was then finally restored to France. There are two settlements, one on the mainland, another on the island of the same name, separated from the former by the river Cayenne, making in all an area of about 27,000 square miles. The mainland is low and marshy, and the Indians in the surrounding territories are so troublesome, that the settlers attend to little else than the rearing of cattle. It is on the island that all the articles of merchandise are raised, consisting of coffee, sugar, cotton, cocoa, indigo, Cayenne pepper, &c. The island is 18 miles long, and 10 broad. At the north point is the town of Cayenne, the capital

of the colony, with a fine convenient harbour, and containing about 200 houses. The population of the whole colony does not exceed 22,000; and altogether it is a settlement of very little importance.

*Dutch Guiana*, until 1814, comprehended Surinam, Berbice, Demerara, and Essequibo; the three last were then transferred to Britain. The remaining province of Surinam is about 210 miles long along the coast, and has an area of about 36,000 square miles. The soil is low, rich, and fertile, and produces sugar, rum, cotton, and coffee, for exportation. In 1842 the population was estimated at 78,000, four-fifths of whom are slaves, free Indians, and Maroons. Paramaribo is the capital, situated on the river of that name, with a population of from 18,000 to 20,000.

### PATAGONIA.

This region is of great extent, occupying the whole southern portion of South America, beyond about the 40th parallel of south latitude. Its length, including Cape Horn, is above 1000 miles; but its breadth at the widest is not much more than one-third of that space, and it gradually narrows to a point at the southern extremity, where the land bends in a curve to the south. The interior of this large territory is but little known; but the more that is ascertained of it, the less does it appear likely ever to become the seat of a thriving people. Terra del Fuego is divided into three islands by two channels, and is altogether a dreary region, inhabited by a few miserable savages.

### FALKLAND ISLANDS.

This insular group, situated in the Southern Ocean, about 300 miles north-east of Cape Horn, consists of two large islands, east and west Falkland, containing upwards of 130,000 square miles, and of ninety islets of various dimensions. The group was discovered by Davis in 1592; and small settlements made at different times on the larger islands by the English, French, and Spaniards were successively abandoned, till in 1833 (when the southern whale-fishery, and the trade to America, rendered the islands of more importance) they were formally taken possession of by Britain. They now constitute a British colony or dependency, under the direction of a governor and council. The only settlement is Port Louis, on the eastern island; the principal production of the colony is cattle; but the surrounding seas abound with excellent fish, seals, and sea elephants. In 1842, the value of the exports exceeded L.1000, and the imports L.400.

## WEST INDIA ISLANDS.

This important archipelago extends from lat. 10° to 23° north, and from long. 59° 30' to 85° west, studding that large indentation of the Atlantic Ocean which lies between North and South America. As a whole, the islands are separated from the former continent by the Straits of Florida, and from the latter by the Gulf of Paria; thus having the Caribbean Sea, the Bay of Honduras, and the Gulf of Mexico, on the south and west, and the Atlantic on the north and east. They are commonly divided into the following groups:—The *Bahamas*, consisting of 14 principal islands, and upwards of 600 rocky islets or cays; the *Greater Antilles*, comprising Cuba, Haiti, Jamaica, and Puerto Rico, with their subordinate islets; the *Caribbean*, including the Virgin, Leeward, and Windward clusters; and the *Lesser Antilles*, lying along the coast of South America. The aggregate area is estimated at 93,000 square miles.

### SUPERFICIAL FEATURES—PRODUCTS.

The general aspect of the West Indian archipelago is mountainous; and following their curving sweep from the peninsula of Florida southwards, they appear to

belong to one great axis of elevation. Many of the islands exhibit manifest proofs of volcanic origin; and they are all less or more subject to violent shocks of earthquakes. In the larger islands the craters seem to be extinct; but in St Lucia, Martinique, Guadaloupe, Montserrat, &c. several of them have thrown out smoke and ashes since the middle of the last century. As might be expected, various degrees of elevation are exhibited in the great chain: thus in Cuba the highest point is 9000 feet; in Haiti 8500; Jamaica 7150; Dominica 6000; Guadaloupe 5500; and in St Lucia 4000. Numerous streams descend from these mountains; and though they do not reach the size of rivers, yet serve to water the fine plains and valleys, whose fertility is mainly owing to their influence. Several of the Caribbean islands, however, are of secondary formation, and not much elevated above the sea; while the Bahamas are generally low, with a scanty soil, and interspersed with numerous coral-reefs and shoals. The mineral products are copper in Cuba, sulphur in Guadaloupe, and pitch from Barbadoes and Trinidad.

Lying almost wholly within the tropics, these islands

CHAMBERS'S INFORMATION FOR THE PEOPLE.

know no winter; the year, as under similar latitudes, being divided into *wet* and *dry* seasons. Nevertheless, meteorologists distinguish four periods—spring, with gentle showers in April and May; the hot and sultry summer from May till October; the autumnal rains, which then begin and continue till December; and winter, from December till April, consisting of serene and cool weather. During the rains, the climate is in several of the islands decidedly unhealthy; but throughout the dry season, nothing can exceed the softness of the air, the brilliancy of the heavens, and the luxuriance and splendour of the vegetation. Between August and the end of October most of the islands are subject to furious hurricanes; these, however, are luckily not very frequent, and are unknown except during this short period.

'The rich and varied productions of the West Indies give them an important place in the commercial world. To their valuable native plants, art and industry have added others not less valuable. The sugar-cane, yielding its threefold tribute of sugar, molasses, and rum; the coffee-plant, pimento or all-spice; the plantain and the banana; the pine-apple, anana, yam, sweet potato, maize, cassava, manioc; with cacao, tobacco, and cotton; various dye-woods and stuffs, as fustic, logwood, indigo; medicinal plants, as liquorice, arrowroot, ginger, jalap, ipecacuanha; building and cabinet timber, as mahogany, lignumvite, and cedar; to which list must be added the bread-fruit, cocon, mango, papaw, guava, orange, lemon, tamarind, fig, and other tropical fruits. The cattle are generally of diminutive size; only a few of the islands contain sheep and goats; few horses, asses, or mules are reared, and consequently great numbers of these are imported from the continent. Hogs are more abundant than other domestic animals. There are few wild animals, but wild swine, tajassoes, monkeys, rats, and some smaller animals. The manati is found in Trinidad and Tobago; the cayman, turtle, and other reptiles are common; and fish are everywhere abundant. Land and sea-crabs are also common; and amongst the more remarkable insects are mosquitoes, cockroaches, scorpions, ants, and the valuable cochineal insect.'

POPULATION—GOVERNMENTS.

The native tribes have long since become extinct, except perhaps a few families in Trinidad. At the time of their discovery by Columbus in 1492, the northern islands were inhabited by the fierce and warlike Caribs, and the northern by the Arrowaaks, a more mild and gentle race. The latter have been described as indolent and sensual in their habits, but mild and forgiving in disposition, affectionate to their wives, and seem to have been of a domestic turn of character. They were particularly fond of dancing and various other peaceable amusements and games. Their form of government was monarchical, the kings being called *caciques*, and their power hereditary. Subordinate chiefs or princes governed each district, who were tributary to the king. They had likewise an established priesthood; but their religion consisted of the usual savage superstition. They, however, believed in the existence of a Deity, and a future state of rewards and punishments. At present, the great mass of the population is of African origin—the remainder consisting of Spaniards, French, English, Dutch, and Danes—who have carried with them their religion, laws, manners, and industry. Reckoning the gross population, which is said to be decreasing, at 3,000,000, about 1,900,000 may be ranked as Negroes,\* 630,000 whites, 470,000 Creoles, and other admixtures. The following table exhibits the names, areas, and popula-

\* Previous to 1834, the British West India islands were all cultivated by Negro slaves; but in that year a bill passed the Houses of Parliament by which slavery was abolished, the planters receiving £30,000,000 sterling as the price of Negro emancipation. This bill declared, that after the 1st of August 1834, all slaves should become apprenticed labourers; the apprenticeships to cease in August 1840.

BRITISH POSSESSIONS.

The forms of government established in the British colonies in the West Indies may be divided into two classes: those having a governor, council, and representative assembly; and those having only a governor and legislative council. The first includes Jamaica, Barbadoes, Antigua, Tobago, Grenada, St Vincent, Montserrat, Nevis, St Christopher's, Honduras, the Virgin Islands, the Bahamas, and the Bermudas; and the second, Trinidad and St Lucia. The governor has the chief civil and military authority; the council is somewhat analogous to the privy-council in this country, and the House of Assembly to the House of Commons. A member of the House of Assembly in Jamaica must possess a freehold of £300 per annua, or a personal estate of £3000; and an elector must have a freehold of £10 per annum in the parish for which he votes. Some of the islands have only lieutenant-governors, who are under the governor of some adjacent island. The lieutenant-governors of St Vincent, Grenada, Tobago, and Guiana, are under the governor of Barbadoes. Their powers, however, are nearly equal to those of a governor. In those islands which have no representative assembly, the legislative council consists of the chief secretary, the treasurer, the chief-justice, the attorney-general, and the commander of the troops. These are appointed by the crown; and sometimes a few of the principal landed proprietors are made members of the council. Several islands are sometimes included in one government, who send their representatives to the island which is the seat of legislature for the time being. Thus, in the Leeward Islands, St Christopher's, Nevis, Montserrat, and one or two other small islands, send their representatives to Antigua, which is the seat

## WEST INDIA ISLANDS.

of government for them all; or, in other words, the residence of the governor. The superior and inferior courts of judicature resemble those in England, the laws being the same, unless as they may be affected by the special colonial enactments passed from time to time. Assize courts are frequently held to expedite the course of justice. There are likewise parish courts, wherein justices of the peace decide summarily in small-debt cases. There are offices where all deeds, wills, sales, and patents, are recorded. All persons intending to leave the island are obliged to give notice at the office of enrolment three weeks before they can be entitled to a pass, or to find security for what debts they may leave unpaid in the island; and for further precaution, masters of vessels are taken bound, under heavy penalties, not to carry off any person without such pass. The procedure of the Assembly follows as near as may be the formula of the British legislature, and all their bills have the force of laws as soon as the governor's assent is obtained. The power of rejection, however, is vested in the crown, but, *until rejected*, the laws are valid. The governor can also refuse his assent to all such laws, and can dissolve and call together the Assembly at pleasure. With these preliminary observations, we proceed to notice the principal islands:—

### Jamaica.

This is the third island in point of size in the western hemisphere, being inferior only to Cuba and St Domingo. It lies about 100 miles south of the former, and about 90 west of the latter. It is 160 miles long, 45 broad, and contains about 4,000,000 acres of land. This island was discovered by Columbus during his second voyage, and was well populated at that period. The natives opposed his landing at first, but he soon effected a reconciliation with them, and took possession of the island in the name of his sovereign. In 1509, the island was formally occupied by Spanish settlers under the command of a deputy-governor; but for many years they were engaged in incessant warfare with the natives. The settlers committed great atrocities on the Indians, whom they at last completely extirpated, not a single native being left alive when the English took possession of the island in 1655, nor, it is said, for a century before. During the period the Spaniards held possession of Jamaica, they appear to have made some advancement in agriculture; but their rapacity for gold, which they were constantly in search of, prevented any great improvement in this department. They, however, cultivated the sugar-cane, the vine, and the cotton-tree, and introduced cattle from Europe. Cromwell greatly encouraged the settlement of Jamaica; and in the course of a few years, the number of whites amounted to 4500, and 1400 Negroes. The population rapidly increased, the settlers being principally soldiers from the disbanded Parliamentary army, and outlaws from the mother country. Numerous importations of Negro slaves also took place, which in 1688 were calculated to amount to 10,000 annually; and from that time till now the population in most of the islands has gradually increased.

Jamaica has been subjected to several dreadful earthquakes; one of which, in 1692, caused almost the entire loss of the town of Port Royal. This town was also reduced to ruins by fire in 1703; and a similar catastrophe took place so recently as 1815. It was also much injured in 1722 by one of those dreadful hurricanes so frequent in tropical climes. The white inhabitants have been repeatedly in danger from the revolts of their slaves, which were the occasions of much bloodshed and cruelty on both sides. The slaves are said to have been at first instigated to rebellion by the Spaniards; but being defeated by their English masters, they fled to the mountains, assumed the name of Maroons, and continued for nearly a century and a-half in constant hostility with the colonists. The most remarkable rebellion broke out in 1795, and which has been known since by the name of the Maroon War. No other event occurred to disturb the peace of Jamaica

until 1831, when an extensive revolt took place from the exaggerated hopes of the Negroes for emancipation. It is remarkable, that during this revolt, although much property was destroyed, no personal violence was offered to any white person, beyond a few hours' captivity. Since the passing of the Emancipation Act, no disturbances of any importance have taken place.

Jamaica is of an oval shape, and presents a greater variety of scenery and climate than any other island in the West Indies. A range of mountains called the Blue Mountains, runs from one end to the other, and rises in some parts to the height of nearly 8000 feet above the level of the sea. These are again occasionally intersected by cross ridges running north and south. At the south end, near the sea, these mountains are in some parts covered with forests, high and abrupt in appearance, and difficult of access. On the other side the hills rise with a gentle acclivity, and are separated from each other by vales, the vegetation of which is described as extremely luxuriant and beautiful. The mountains are generally of a conical form, very steep, and approaching on the north side very near to the sea. The deep ravines between the lofty mountains are densely covered with woods, and are denominated 'cockpits.' These offer a striking contrast to the lower mountains, where the coffee-plant, pimento, cotton, &c. are cultivated. On the south side, the mountains are situated a little distance from the sea, leaving plains of about twelve miles wide.

There are numerous rivers in Jamaica, two hundred of which have been enumerated; but none, owing to the irregular nature of the country, are navigable for vessels of any burthen. They are extremely valuable, however, in the cultivation of the soil; the great height from which the water runs allowing it to be carried a considerable length in irrigating the country, and turning mills upon plantations. The rapidity of the current also prevents it from stagnating; and thus it is kept pure for animals to drink from its source to the ocean. There are sixteen principal harbours, which afford secure havens for shipping, and about thirty bays or roads with good anchorage.

The soil of the country is generally deep and fertile, presenting a shining appearance to the eye when first turned up. In some parts it is of a chocolate colour; in others a bright yellow, and even scarlet. The best soil for cultivation is what is termed the brick-mould, which is of great depth, so rich as to require no manure, and of a quality which seems well suited for the climate. It is so far retentive, that in dry weather it retains enough of moisture for the preservation of the plants, and so porous as to admit of the superfluous water sinking through it during heavy rains. This soil is composed of clay, sand, and black mould, and is thought the best soil in the island for the cultivation of the sugar-cane. The next soil in point of fertility is the black shell-mould; and there are many varieties throughout the island all more or less fitted for cultivation. A rich lead ore is found in some parts of the country, which is impregnated with silver. This ore is worked at Liguana; and varieties of copper, striated antimony, and ironstone, have also been obtained.

Jamaica is divided into three counties—Middlesex, Surrey, and Cornwall. The seat of government is Spanishtown, in the county of Middlesex, situated at the extremity of an extensive plain. The mountains closely approach the town, and the river Cobre runs past it, at a distance of about a quarter of a mile. The town is not large, but the buildings are very magnificent, being built in the style of Spanish architecture. Kingston is the most important town in the island, and is generally considered as the capital, although not nominally so. It is situated upon a gentle inclined plain, which is enclosed on the north by the Liguana ridge of mountains. These mountains form a sort of semi-circle, and the plain stretches down to the harbour, which is amongst the finest in the world. It affords excellent anchorage all round, and the largest merchant ships can ride close in shore. This harbour is

defended by numerous batteries, and is considered perfectly unassailable from the sea. The streets of Kingston are built with the greatest regularity, somewhat in the style of the New Town of Edinburgh. The houses are principally of wood, and in general two storeys high, with verandas above and below. The town contains about 40,000 inhabitants, of whom 12,000 are whites, and the rest people of colour. Montego Bay, situated on the opposite side of the island from Kingston, is a seaport of some importance. It lies at the foot of a range of mountains which nearly surround the town, and possesses a neat church and commodious barracks. Falmouth is situated about fifteen miles east of Montego, and is rising rapidly to importance. The harbour in the inside is deep and well sheltered, but the entrance is intricate, and not more than 17 feet deep across the bar. The town is built on the west side of the harbour, and possesses several good public buildings. There is more produce shipped from this port than from any other in the island after Kingston.

Trinidad.

This island, the next in importance to Jamaica of the British West India possessions, is favourably situated at the mouths of the large river Orinoco; being separated from the continent of South America by the Gulf of Paria. It is 90 miles long and 50 broad, with an area of 2400 square miles. It was discovered by Columbus in 1498, and was colonised by the Spaniards in 1588, at which time it was well populated with Caribbs, who were of a mild disposition and industrious habits. The native inhabitants, however, were soon either destroyed or sent to the continent of America to work in the mines by the Spaniards. The island belonged to Spain until 1797, when it was taken by the British, and has ever since remained a colony of this country.

Along the south and north sides of this island run two ridges of mountains, extending nearly across the country, and along the north shore, giving it the appearance at a distance of being nothing but an immense line of rocks. The western side for some distance is flat, richly wooded, and is described as presenting a most beautiful appearance. The high mountains of Cumana on the American continent are visible from this side; and when viewed from a height, with the Gulf of Paria, and the beautiful verdure of the island, present a picture which is scarcely to be equalled. The centre is diversified with many finely-wooded hills, and valleys of the greatest fertility. The highest land lies on the north side, and in some parts reaches 3000 feet in height. The other mountains are not of any great elevation, but they are all thickly covered with wood and pasture. There are numerous rivers in this island, several of which are navigable for ships of some size. The best harbour in the island is that of Port Royal, after which Port-of-Spain, which has the most extensive bay in the world; and all around the west coast there are numerous bays, which afford good anchorage for shipping. Several craters exist in Trinidad, some of which give occasional indications of not being quite extinct. Mud volcanoes also occur, the largest of which is 150 feet in diameter. The mud never overflows, but remains always within the surface of the crater; and when one crater ceases to act, another appears in its vicinity. The celebrated pitch lake is situated on a small peninsula, about eighty feet above the level of the sea. The pitch has usually the appearance of pit coal, but is gray in colour, and somewhat hard, except in very hot weather, when it becomes liquid to a small depth. The lake is about a mile and a-half in circumference, with several small islands covered with trees, and the country around is wooded to its banks. The soil of Trinidad, generally speaking, is good; the only barren parts being the sandy plains, and these occasionally afford pasturage for cattle. The sugar-cane, coffee, and cocoa are cultivated to a considerable extent, and the produce is increasing very rapidly. Several spices have also been introduced, such as the nutmeg, cinnamon, and clove.

The capital of the island is Port-of-Spain, which is said to be one of the finest towns in the West Indies. The streets are wide, and intersect each other so as to catch every breeze. The houses are all built of stone, none being allowed to be erected of wood. There are also numerous other ports around the island, which are gradually rising in importance.

Tobago.

This island is about 82 miles long and 12 broad, and is the most southerly of the West India Islands. It is about six miles distant from Trinidad, at the east end, and about sixty miles from Grenada. Tobago was discovered by Columbus in 1496; and in 1580 it was taken possession of by the English. It was afterwards settled by some Dutch colonists; and after many takings and retakings, it was ceded to Britain at the peace of 1763. In 1781 Tobago was captured by the French, but was retaken in 1793 by the British, with whom it has ever since remained. Its appearance from the north is gloomy and mountainous, being principally composed of conical hills and ridges, which in some parts reach the height of 1800 feet. The north-west is the least mountainous, and the south is diversified with occasional hills and rich valleys. There are a number of small streams, which, rising in the hills, water the low country down to the sea. The natural harbours in this island are numerous, and several of them adapted for ships of the largest class. The chief town is Scarborough, situated on the south-west side. It is built without much regard to regularity, and is about half a mile from Fort King George, the principal military station. The soil is rich, and the produce as varied as that of any of the other islands.

Grenada and its Dependencies.

This beautiful island is situated about sixty miles from the American coast; is 25 miles long, and 12 at its greatest breadth, and contains 80,000 acres of land. It was discovered by Columbus in 1498, but was not settled till 1650, when a party of French from Martinique took possession of it. It was taken from the French by the British in 1762; again retaken, but finally ceded to Britain in 1783. The face of the country is hilly, irregular, and extremely picturesque. There are a number of rivers, none of which are of any great importance for commercial purposes, but all useful for irrigating the country. Several hot springs exist; and a fresh-water lake, 2½ miles in circumference, is situated at an elevation of 1740 feet above the level of the sea. The capital is the town of St George, situated within an amphitheatre of hills. The houses are well built, of stone or brick, and the streets wide and well ventilated. The harbour is spacious, protected on all sides from hurricanes, and is said to be capable of containing 1000 ships. Cotton was formerly the chief article produced on this island, but sugar, cocoa, and coffee are now also cultivated.

The Grenadines are a group of small islands running towards St Vincent, the largest of which are Carriacou, Bequia, Canuan, &c. Several of these islands are inhabited, and produce sugar, cotton, fruits, live-stock, &c. in great abundance.

St Vincent and its Dependencies.

This is thought the most beautiful of the Caribbean islands. It is about 24 miles long and 20 broad; fifty-five miles west of Barbadoes, and about the same distance from Grenada. It was discovered by Columbus in 1498; was first settled by the French; captured by the British, and retaken; but finally ceded to this country in 1783. Its character is decidedly volcanic, traces of rocks which have undergone the action of fire being everywhere visible. The mountains are high and sharp at the top, running from north to south, with deep valleys between. The soil is of a strong loam in the valleys, but assumes a more sandy nature on the hilly ground. In 1812, St Vincent was visited by a severe volcanic eruption, the matter from which nearly

## WEST INDIA ISLANDS.

covered the whole surface of the island. The damage done to the island was not great, but fifty persons lost their lives on the occasion. The island is divided into five parishes, of which the principal is St George, in which the capital, Kingston, is situated. The houses of the town are built of stone in the lower storeys and wood in the upper; and there are many commodious public buildings, but none of them of any great elegance. There is a famous botanic garden about one mile from Kingston, occupying about thirty acres of ground, and containing a fine collection of tropical plants. The most celebrated object in this island is the Souffriere, a volcano, the crater of which is 3 miles in circumference and 500 feet in depth. The climate is thought very healthy; but hurricanes are frequent, and sometimes very destructive. There are eight small islands adjoining to St Vincent, which are cultivated; but they are not of such importance as to warrant particular mention.

### Barbadoes.

This is the most easterly of the Caribbean islands, and was the first settlement made by the British in the West Indies. It is about 22 miles in length and 14 in breadth, containing an area of 106,470 acres. The period of the discovery of this island is unknown, the first mention made of it being in 1600. It was colonised by the British in 1625, Charles I. having made a grant of it to the Earl of Carlisle, who encouraged emigration to the island. A society of London merchants accepted of 10,000 acres on certain conditions, and sent out a governor of their own. After this the settlers increased very rapidly; and in 1650, it was computed that there were upwards of 20,000 British in the island. During the Commonwealth, an armament was fitted out by Cromwell against Barbadoes, for adhering to the royal cause, which committed great depredations against the inhabitants; and since this time the population has rather decreased. The island is generally level, except in the north-east quarter, and here, in some parts, the hills reach the height of 1100 feet. It has a beautiful appearance, from the land being well cultivated and the vegetation luxuriant. The soil is good, varying from a rich deep mould to a light sand, and a red clay of considerable depth is occasionally found. There are a number of springs in the island, one of which casts up a bituminous matter called Barbadoes tar, and another emits a stream of sulphuretted hydrogen gas, which can be ignited. Oxen, horses, and other cattle are plentiful, the first being most generally used for labour. Considerable numbers of hogs and poultry are reared; and, indeed, this island is distinguished from most of the West India colonies by the quantity of provisions which are raised, the inhabitants depending little upon foreign supplies.

Bridgetown, the capital, is situated on the shores of Carlisle Bay, and contains about 20,000 houses. The town is well laid out, many of the houses are very handsome, and spacious barracks occupy the southern extremity. The climate is considered healthy, but would feel extremely hot were it not for the constant trade-winds. The island is subject to hurricanes, one of which in 1780 laid waste its whole extent. The loss of lives on this melancholy occasion was estimated at 3000, and property valued at upwards of £1,000,000 was destroyed. Barbadoes seems to have reached the height of its prosperity at the end of the seventeenth century, and since that time the population has decreased.

### St Lucia.

This island is about 32 miles long and 12 broad. The English were the first who made a settlement in St Lucia, but the colonists were completely destroyed by the natives. It was again settled, and since that time has passed repeatedly from the British to the French, until 1803, when it was captured by the British, in whose possession it has ever since remained. This island is traversed longitudinally, or from north to south, by a ridge of lofty mountains, which terminate in most fantastic peaks. These mountains are

densely wooded, and at times, from the attraction of the trees, are completely enveloped in clouds. On the west coast there is an excellent harbour called the 'Little Carenage,' which, admitting only one ship at a time, is capable of containing thirty ships of the line. The island is divided into Basseterre, the low or leeward country, which is the best cultivated district, and Capisterre, the high country. Both of these districts are considered unhealthy; the first from the abundance of stagnant water, and the other from the denseness of the woods. As cultivation proceeds, however, these causes will be removed, and the island rendered as healthy as any in its neighbourhood. The capital is Castries, which is the only town in the island, and a place of no importance. There is a small island called Pigeon Island about six miles from St Lucia, which is considered a healthy and important military station.

### Dominica.

This island is situated between the French colonies of Martinique and Guadeloupe, and is about 29 miles in length and 16 in breadth, containing nearly 186,436 acres. It was considered a neutral island until 1759, when it was taken possession of by the British, with whom, after being repeatedly taken and retaken, the island still remains. Dominica is of volcanic origin, and has many lofty mountains, the highest of which is 5314 feet above the sea's level. Several of these mountains contain active volcanoes, which frequently discharge vast quantities of burning sulphur; and there are many hot-water springs throughout the island. The valleys are fertile, well watered with thirty fine rivers and numerous smaller streams. The trees are lofty, affording the finest timber, such as locust-wood, rose-wood, mastic, iron-wood, cinnamon, bastard mahogany, and a gum-tree of considerable value. Domestic animals are very abundant throughout the island; and indeed all European animals succeed extremely well in this place. In the woods are innumerable swarms of bees, which lodge in the trees, produce large quantities of both wax and honey, and are said to be identical with the European bee. The capital is Charlottetown, situated in the parish of St George. The streets are spacious, well paved, and from the heights above the town look new and clean. The roadstead is open to the hurricanes, which frequently occur from August to October, but otherwise safe. Prince Rupert's Bay is the safest harbour in the island, and is said to be capable of containing the whole British navy.

### Montserrat.

This is one of the smallest of the British West India Islands, being only about 12 miles long and  $7\frac{1}{2}$  broad. It was discovered by Columbus, first settled by the English, and taken once by the French; but has ever since remained a colony of this country. Montserrat appears to be of volcanic origin, and presents a very uneven and mountainous surface. It is extremely difficult of access from the broken character of the land, and the coral beds and rocks which stud the sea around the southern part of it. The mountains are in many places inaccessible, and seem to have been separated from each other by some strong convulsion, from their banks being so precipitous. Both mountains and valleys are covered with wood; and many fine streams water the low lands. The capital is Plymouth, a small but well-built town, the houses of which are constructed of stone, and exceedingly comfortable. Indigo was formerly much cultivated in this island, but this article has been abandoned; and the principal productions now are cotton and sugar, the latter of which is much esteemed. This island has been called the Montpelier of the West Indies, from the healthy nature of the climate, although occasionally subject to hurricanes.

### Antigua.

This island, which was discovered by Columbus in 1493, is about 20 miles long, 54 in circumference, and contains an area of 69,277 acres. It was first settled

in 1682 by the English, but its progress was slow at first, in consequence of the want of water. Antigua is somewhat oval in shape, indented with many bays, and surrounded with small islands, rocks, and shoals, which render it difficult of access. The face of the country in the north-east part is low, and even marshy, but it gradually rises towards the south and west. None of the hills are of any great elevation, the highest being little more than 1200 feet above the sea's level. The island being almost destitute of water, the colonists are obliged to have tanks to collect the rain which falls during the wet season. The land, however, is very fertile, and vegetation in every part luxuriant. Tobacco was formerly much cultivated, but the sugar-cane has entirely superseded this commodity; and there are several medicinal plants produced on the island, such as the aloe, quassia, &c. The capital, St John's, is situated on the north-west, and possesses an excellent harbour. Englishtown, on the south, is the next town which has a fine harbour, with a royal naval-yard, arsenal, and conveniences for careening ships. The whole coast is indented with bays, which, although difficult of access, afford excellent shelter to shipping. The climate is dry and healthy; and the island is not subjected to either heavy dews or severe hurricanes, like most of the other islands. Antigua is ruled by a governor, who is also commander-in-chief over Montserrat, Barbuda, Anguilla, St Christopher's, Nevis, the Virgin Islands, and Dominica; with a legislative council and House of Assembly. Antigua was the first island to ameliorate the slave laws, by affording the accused the benefit of trial by jury; and an act of Assembly, 13th February 1834, decreed the emancipation of every slave without requiring the period of apprenticeship prescribed by parliament.

St Christopher's or St Kitt's.

This island, situated in latitude 17° 18' and longitude 62° 40', is 72 miles in circumference, and contains 68 square miles. It was discovered by Columbus, who is said to have given it his own name; and it was first settled by an Englishman of the name of Warner, and fourteen associates. Warner found several Frenchmen already on the island; and these two parties, after making war upon the natives, divided the island between them—one part, called Capisterre, or high country, being assigned to the French; and the other part, called Basseterre, or low country, given to the English. Many bloody battles were fought between these two parties until 1713, when the whole island was ceded to Britain. St Christopher's is of an irregular oblong shape, divided from north to south by a ridge of mountains; and the whole land of the island is somewhat elevated, sloping gradually from the centre to the sea. The greatest height is Mount Misery, which rises 3711 feet, almost perpendicularly, and is clothed with vegetation nearly to the summit. There is no plain in the island which can be called swampy, the gradual fall of the ground carrying off any superfluous moisture from the earth. The vale of Basseterre is described as extremely beautiful, the ground being very rich, and everywhere highly cultivated. The soil is chiefly of a dark-gray loam, lying upon a bed of ashes, very porous, and is considered the finest soil for the cultivation of the sugar-cane in the West Indies. There is said to be a sulphur mine in one of the mountains of the centre, and another of silver; but it does not appear that these have ever been worked. The island is watered by four rivers, none of them of any size; and there are numerous springs in the low lands. These, however, from strong saline impregnations, are not fit for drinking, and the inhabitants have to collect rain water in tanks for domestic purposes. The capital is Basseterre, which is the best shipping station.

Nevis.

This beautiful little island, consisting only of a single mountain, which rises like a cone out of the sea, green, unbroken, and verdant to the summit, was discovered

by Columbus at the same time with St Christopher's, from which it is separated by a channel about 2 miles broad. It was first taken possession of by a party of English from St Christopher's; and the population is said to have rapidly increased. The mountain of which Nevis is composed is about 4 miles in length and 3 in breadth; its area being about 20 square miles. The hill is well cultivated; and at the height where cultivation ceases, evergreen forest-trees grow luxuriantly, the whole island having a cheerful picturesque aspect. The capital is Charlestown, which is described as a neat well-built town, with several handsome public edifices.

Barbuda and Anguilla.

These two islands, although far separated, may properly be classed together, from the similarity of their scenery and the occupations of the inhabitants. Barbuda is situated about twenty miles north-east of St Christopher's, and ten north of Antigua. It is about 20 miles long and 12 broad. The first notice made of Barbuda is in the time of Queen Anne, when it was given in perpetual grant to General Codrington and his descendants, by whom the greater portion of it is still possessed. Anguilla, or Snake Island, is about 100 miles north of Barbuda, and the same distance north-north-west of St Christopher's. It is 30 miles long and 3 broad, and receives its name (signifying an *eel*) from the peculiarly winding shape it presents. These islands were both first settled by the British; and although subject to occasional attacks from other powers, they have always remained in the possession of this country. The interior aspect of these two islands is quite different from that of any of our other West Indian settlements, being in many respects indeed quite *English*. The sole occupation of the inhabitants is rearing stock, and cultivating provisions, for which a ready market is found in the neighbouring islands.

Virgin Islands.

This name was given by the discoverer Columbus (in 1493) to a group of about forty small islands, lying to the northward of the Leeward Caribbean Islands, and between them and Puerto (or Porto) Rico. They extend about 24 leagues from east to west, and about 16 from north to south. They are divided between the British, Danes, and Spaniards, but much the larger and more valuable number belong to the former. The British Virgin Islands were first possessed by a party of Dutch buccaners, who built a fort on Tortola, but they were expelled soon after by a party of English. They have remained in the possession of this country ever since. The largest of these islands is Anegada, the next Tortola; and although never considered of any great importance, they afforded excellent shelter to shipping during the late war. Tortola is mountainous, the interior containing large tracts of waste land difficult of access. The soil is thin, and not well-suited to the cultivation of the sugar-cane, although this and cotton are the chief articles of produce. The harbour of Tortola is very extensive, completely landlocked, and has afforded shelter in many cases during the war to 400 vessels. Anegada, although the largest island in extent, is of little importance, only a very small portion of it being under cultivation. It is surrounded by a reef which renders it difficult of access, and the other islands being so near, it is little frequented. Virgin Gorda is of an irregular shape, and contains two good bays, where ships may ride in security. The soil is of a light sandy nature, and the chief articles of produce are sugar, indigo, tobacco, and cotton. These islands are subject to the government of St Kitt's, with a council and assembly of their own.

The Bahamas or Lucayas Islands.

These are the most northerly of all the West Indian islands, stretching towards the coast of Florida, and forming with it the channel called the Strait of Florida. They were the first land discovered by Columbus in

## WEST INDIA ISLANDS.

1492, and amount in number to fully 500. The island which gives the name to the whole is the most northern, as well as the most important of the group. A settlement was established by the British in 1629, which was ravaged by the French and Spaniards several times, and the group of islands became a nest for pirates, until the beginning of the last century, when they were expelled by the British. The Bahamas are evidently of coral formation, and although flat, they have a very pleasing aspect, from the richness of the vegetation. The chief island is New Providence, which contains the capital Nassau. These islands are very healthy, and from their situation the climate is delightful, being of a medium temperature. The chief article produced for exportation is cotton, neither sugar nor coffee having succeeded. Provisions of all sorts are very plentiful, cattle and sheep thrive well, and the shores abound with fish and turtle.

### Bermudas, or Somers' Islands.

These are a small cluster of islands, lying almost in the shape of a shepherd's crook, in latitude 32° 20', and longitude 64° 50', distant about 600 miles from the nearest point of the American continent. Their discovery was owing to the shipwreck of Juan de Bermudes, a Spaniard, who was driven ashore upon these islands while on a voyage from Spain to Cuba. The same fate happened to Sir George Somers, an Englishman, in 1608, who was the first to colonise the Bermudas. They are upwards of 300 in number, contain about 14,000 acres of land, and are so much alike in character, that to describe one is to describe the whole. The principal islands are St George, Ireland, St David, Somerset, Long and Birds' Islands, &c. These lie close together, in such a way as to form capacious bays, which afford good anchorage when once got into. The coast, however, is of the most dangerous description, being thickly studded with rocks, which are visible at low water, and disappear at flood tide. The chief articles of produce consist of arrowroot, coffee, cotton, and indigo. The soil is very fertile, and produces many kinds of vegetables fit for food; and medicinal plants, such as the aloe, jalap, &c. grow spontaneously. The whale is an annual visitor to the coast, the catching of which forms a lucrative employment to the inhabitants. Bermudas possesses no fresh-water streams, and only a few wells, the water of which is brackish; but there are a great many tanks which fill during the rainy season, and supply the inhabitants. The climate is not considered healthy, the yellow fever being of frequent occurrence. The Bermudas have never been considered of great importance to this country; but they are likely to become more so in consequence of their being formed into a penal settlement.

Notwithstanding their richness and fertility, the favours conferred by the mother country, and the exertions of British industry and capital, our West Indian possessions are at present far from being in a prosperous condition either as regards produce or trade. In 1831 the exports amounted to £8,000,000, and in 1841 to less than £6,000,000. In 1831 about 4,000,000 cwts. of sugar were exported; in 1841 scarcely 2,000,000. In 1831 the exports of rum exceeded 7,000,000 gallons; in 1841 less than 3,000,000. In 1831 there were upwards of 20,000,000 lbs. of coffee exported; in 1841 less than 10,000,000. The imports from Britain alone in 1842 amounted to £2,591,425; in 1843 to £2,882,441; in 1844 to £2,451,477; in 1845 to £2,789,211; and in 1846 to £2,505,587; thus exhibiting no increased capability on the part of the population to purchase those luxuries and necessities which they do not and cannot manufacture for themselves. This unsatisfactory state of matters some attribute to emancipation and the difficulty of procuring cheap and efficient labour; but others, who take a more English and business view of the subject, are inclined to impute the whole to absenteeism and expensive living on the part of the planters, who are thus compelled in most instances to mortgage

their estates on disadvantageous terms, and ultimately to submit to a ruinously-expensive system of management by law agents, factors, and the like, instead of personally superintending and combatting with the difficulties attendant upon the introduction of free labour in an economical and skilful manner. Be this as it may, what with military and civil expenses, what with buying from these planters under high protective duties—to say nothing of trouble and obstruction to home affairs—we are annually losing by our West India connection several millions per annum.

## FOREIGN POSSESSIONS.

### French.

The French possessions in the West Indies comprise the islands of Martinique, Guadaloupe, Marie Galante, and Désirade. Martinique is situated at the entrance to the Gulf of Mexico, and is about 50 miles long and 20 broad, and 140 miles in circumference. It is of volcanic origin; romantic in appearance; and the mountains are covered with almost impenetrable woods. Martinique is well watered; and the soil is good, although it varies much on account of the volcanic eruptions, which have in some places covered the surface of the land. About two-fifths of the whole island are cultivated; the rest being occupied with mountains, forests, and plains, which latter yield good herbage for cattle. Port Royal, the capital, is situated on one of the several bays which indent the coast, and possesses the safest and most capacious harbour in the West Indies; population about 7000. The chief commercial town is St Pierre, which is described as exceedingly neat: population 30,000.

Guadaloupe is situated in lat. 16° 20' north, and long. 62° west. It is divided through the centre by a small channel, which is navigable for vessels of fifty tons, and forms, as it were, two islands. The eastern division, called Grandterre, is 14 leagues long, and 6 broad; and the western, Basseterre, is 15 leagues long and 14 broad. There are several volcanic mountains in Guadaloupe, one of which still emits smoke, and sometimes sparks of fire. The island is well watered, and diversified with hills and valleys. The soil is good, and yields abundance of fruits and grain. The chief productions are sugar—which, although the cane reaches a great height, is not good—and coffee, which is also of an inferior description. The capital is Point à Pitre, which possesses a spacious port. Basseterre is also a considerable town, with many fine buildings.

Désirade and Marie Galante are small islands, situated near Guadaloupe, and subject to its government. The former is famous for its cotton, and the latter yields chiefly sugar and coffee. These islands, along with Guadaloupe, contain about 335,000 English acres, with a mixed population of 120,000 inhabitants.

### Spanish.

A few years ago the colonial possessions of Spain extended from the frontiers of the United States almost to Cape Horn. Now, she has not a foot of land on the American continent; and of the islands, is possessed of only two worth mentioning—Cuba and Porto Rico.

Cuba is by far the largest island in the West Indies, being 700 miles in length and 117 at its greatest breadth. It is traversed throughout its length by chains of mountains, some of which reach the height of 8000 feet above the level of the sea. From these mountains flow numerous streams which water the soil, and render it highly productive of all tropical vegetables. The savannas, or plains, are very extensive, stretching on both sides from the mountains to the sea. The soil of these plains is so fertile, that two, and even three, crops of grain have been cut annually; and during the whole year the fields are covered with plants in blossom. The island is very rich in minerals, particularly copper, iron, and leadstone; and mines of gold and silver have also been worked. Coal-mines have likewise been opened, but it does not appear that they

have been worked to any extent. Cuba was for a long time little cultivated by the Spaniards, being looked upon more as an intermediate station between the mother country and her American possessions, than as a valuable colony. Its position, commanding the entrance to the Gulf of Mexico, gives it great commercial importance; and since the ports were opened to foreigners, the productions and trade of the island have greatly increased. The chief exports are sugar, coffee, and tobacco, which, manufactured into cigars, is in high estimation. The capital is Havana, situated on the north side of the island, and the finest city in the West Indies. It possesses a splendid harbour, which, although narrow at the entrance, is without bar, and, inside, is capable of containing 1000 ships. The other towns in Cuba are Trinidad on the south, Mantanzas on the north, Santiago de Cuba on the east, and Villa del Principe in the heart of the island.

Porto Rico, the only other island belonging to Spain, is situated about twenty-five leagues to the eastward of St Domingo. It is about 90 miles long, 33 in average breadth, and contains 2970 square miles. It is intersected by a chain of lofty mountains, which run through it lengthwise, and possesses table-lands and valleys of great fertility. The island is well watered by rivers, some of which are navigable for two or three leagues from their mouths; and they all abound in excellent fish. The soil on the east and north is rich in pasturage, and numbers of horned cattle are reared by the inhabitants. That on the south side is well adapted for the raising of sugar; but the climate is often very dry, and the land parched. The climate of this island is somewhat peculiar; on the north coast it often rains during the whole year, while on the south coast, an entire want of rain for twelve months is no uncommon phenomenon. The chief productions are sugar, coffee, indigo, rice, and live-stock. The principal towns are Mayaguez and Aguadilla.

Dutch.

The Dutch possessions in the West Indies are Curaçoa and St Eustatius, the islet of Saba, and part of St Martin—all in the Caribbean group. The two former are naturally barren. Curaçoa, from its proximity to South America, was formerly a place of great contraband traffic; but since the independence of that continent, it has ceased in a great measure to be an entrepôt. It is 30 miles long and 11 broad, and produces sugar and tobacco. Like some of its sister isles, it is entirely dependent on the rains for a supply of water. It was held by the Spaniards until the year 1632, when it was taken by the Dutch, in whose hands it has since remained.

St Eustatius consists of a single mountain, which is 29 miles in circumference, and cultivated to the very summit. The productions are sugar and tobacco, and the population may be about 15,000. It was first colonised by the Dutch in 1635, and continued for many years a subject of contention between them and the French, by whom it was alternately possessed, until 1781, when it was captured by Admiral Rodney. The booty which fell into the hands of the English on this occasion was estimated at £4,000,000 sterling. It was restored to the Dutch by the peace of 1795; and after being again captured by the English, was finally secured to the Dutch by the peace of 1814.

The small islands of Saba and St Martin are too inconsiderable to require further mention.

Danish.

The Danish settlements, all belonging to the Caribbean group, are three in number—St Croix (or Santa Cruz), St Thomas, and St John, of which the former alone is of any importance. It is about 81 miles square, and contains about 30,000 inhabitants. The soil is fertile and well cultivated, producing sugar, rum, and tobacco. St Thomas is about 6 leagues in circumference, and St John about the same. They are both quite inconsiderable.

Swedish.

The only colony belonging to the Swedish government is the small island of St Bartholomew, about 15 miles in circumference. It has only one town and one harbour—namely, Gustavia and Le Carenage.

INDEPENDENT ISLAND.

St Domingo.

This island, lying between Porto Rico on the east and Jamaica and Cuba on the west, is 390 miles long, and from 60 to 150 miles broad. It was discovered by Columbus, who called it Hispaniola, or Little Spain; but the native inhabitants call it Haiti, or the mountainous land. The French and Spaniards took possession of the island in 1650, dividing it between them. No particular event took place till the period of the French Revolution, when, taking advantage of the contest between the royalists and republicans, the natives and slaves rose in a body, massacred the whites, and established their independence. Christophe, formerly a slave, was elected chief, and governed the island with great wisdom for a number of years. In 1811, he was crowned king, created princes and nobles, and reigned undisputed till 1820, when his jealousy and despotism caused a general revolt, and seeing his affairs desperate, he shot himself. A republic was then established, which was soon extended over the whole island, the Spanish half having also made a successful revolt. The government at present consists of a president, a senate, and chamber of representatives.

The greater part of the coast of St Domingo is rocky and dangerous; but the bays of Samana and Neyba afford secure anchorage for large ships. There are also many ports, situated generally at the mouths of rivers, in which small vessels can anchor with safety. The rivers are numerous, the principal being the Haina, the Nigua, the Neyba, and the Yima, which are navigable for some leagues from their entrance. The country is mountainous, but interspersed with fine plains of great fertility. The mountains intersect the island from east to west, some of them reaching the height of 6000 feet above the level of the sea. On the north-west side is an extensive plain, supposed to be 80 leagues long, and from 10 to 15 broad, which is extremely fertile, being watered by numerous streams. The soil is of the finest description, and is distinguished by the variety of its vegetable productions—such as cabinet and dye-woods, building timber, drugs, cotton, sugar, tobacco, and almost every species of tropical fruits. The French and Spaniards introduced breeds of horned cattle, hogs, sheep, horses, mules, and asses, which have multiplied exceedingly, and are of great value to the inhabitants. Mines of gold, silver, iron, and copper were formerly found, but it does not appear that they are worked to any extent at present.

St Domingo was formerly considered one of the most important islands in the West Indies, and it is evident, from its size and the fertility of the soil, that it might be made so again. The policy of the government, since the independence of the island was declared, has been illiberal; heavy burthens are imposed upon merchants settling in the country; and all foreign merchandises is liable to a duty of 12 per cent. upon entering the country, except French, which pays 6 per cent. Sugar and coffee were formerly exported in very large quantities, but these have now very much decreased. The exportation of wood has increased as that of sugar and coffee have declined, and tobacco is also more extensively cultivated. The population of the island has diminished considerably since the revolution. Port-au-Prince, the capital, is situated in the department of the west, has an excellent roadstead, and is the chief seat of trade. The town is built of wood; the streets are unpaved; and from the marshy nature of the surrounding country, it is very unhealthy in summer. The population is about 15,000. The other towns are Port Haitien, which is the best-built place in the island, Les Cayes, and St Domingo.

## THE HUMAN MIND.

THE mind of man has in all times ranked among the most important subjects of human knowledge and inquiry. Besides being a wonderfully-framed and highly-complicated piece of work—infinite in faculty and noble in reason, the mirror of the vast universe without—it is the only seat of human feeling and conscious existence, the exclusive dwelling-place of joy or wo.

There are three great distinct sources of knowledge respecting the human mind, and these are also the avenues open to us for controlling its workings:—

I. Outward appearances, actions, and works, and the traces and results of these that are permanently engraved upon the face of external nature. The inner workings of the mind are displayed to some extent in the outward movements of the body, in the features, looks, utterance, gestures, and movements, or in what is called the natural language of man. But the acts and operations directed upon external things are a still more decided class of indications of the character of the mind. The nature of the appetites is shown by what is visibly seized and devoured; the instincts are made known by the actions that each creature is observed to perform on the material within its reach, as the capabilities of a machine are understood from the effects that it can produce; the various passions and emotions may be studied through their various stages by noticing the object that excites them, the agitation and expression of the bodily frame, and the mode of reaction upon the exciting cause. Anger, gratitude, affection, reverence, are all seen under external appearances, and by these they may be distinguished and described, and their causes and effects ascertained. The acquired habits, and the various characteristics of memory, reason, intelligence, belief, conscience, are shown in the same outward way. A child is observed one day attempting to repeat some act that it sees others doing, the next day it has improved in its attempts, and in a short time longer it succeeds in the operation; in which we discern the capacities of observing, imitating, and acquiring new powers that are inherent in human nature. All the processes and works which are performed upon the material of the world are so many signs or pieces of information as to the powers of the human mind acting through the bodily organs. The faculties of digging, house-building, spinning, and of shaping tools to overcome the powers and resistance of the inanimate world, the adaptation of means to ends, and the application of the experience of the past to the guidance of the future, can each be read in clear outward characters, like the rising of the sun, the course of the seasons, or the flow of rivers to the sea. And in consequence of the permanence of many of the products of human labour, the purposes, capabilities, and employments of departed generations may be made apparent to the view. The remains of cities, fortifications, temples, sepulchres, market-places, and highways, are so many indications of the character and pursuits of the men who built and occupied them; and we never hesitate in inferring the one from the other. On the faith of such relics we ascribe taste, imagination, genius, grandeur of design, and laborious perseverance to one people, a low order of inventive power to another, and servility under a despotic government to a third. The creation of the industrial arts, the organisation of armies, the building up of the institutions of civil society, the worship of the supernatural powers, the investigation of nature, the invention of literature and art, are all expressive of what is in man; and they have always been referred to as examples and illustrations of the wants, desires, capacities, and endowments of the race. So that from the whole it must be appa-

rent that the ordinary actions and labours of living beings, the things that are seen to attract, repel, or in anyway influence them, their outward manifestations under every variety of circumstances, the innumerable works that they are observed to engage in, or leave traces of behind them, form an abundant source of the knowledge now under our consideration; in a word, the drama of human life, the transformations effected on the face of the external world, the history of mankind, and the entire aggregate of civilisation, combine to teach us what the mind of man is.

II. The second source of our knowledge of mind is one that has been too much looked upon by metaphysicians as the main source—namely, consciousness, or the immediate feeling of the mind's doings, which is a part of its nature. The works that a man leaves behind him express a sum-total of desires, purposes, and capacities, rather than the detailed current of emotion and thought. In order to reduce the trains of mental working to their smallest individual steps or links, we must attend to our own consciousness. The great results of the human understanding may be seen in the published thoughts, discoveries, and transactions of thinking men; but the ultimate laws that govern its operations cannot easily be traced from these, although, when discovered, they may be confirmed and illustrated by such results. The structure of the imagination could not be so readily derived from the 'Paradise Lost' as from the comparison of that great example with the consciousness that we have of the workings of the faculty in ourselves. Hence we are to regard the impressions left by the mind of its own sensations, thoughts, emotions, actions, and volitions, and capable of being revived and considered like any other impressions, as one of the means of ascertaining the laws and processes and general structure of this part of our nature.

III. The last great source of our knowledge of mind is the anatomy and physiology of the human framework, or everything that can be ascertained respecting the structure of the human system. A certain number of the bodily organs are directly subservient to the operations of the mind, and the mechanism of such organs will therefore be in some measure a clue to these operations. The eye, the ear, the voice, the hand, are all prominently associated with the susceptibilities and activities of the mind; the whole of the movable members of the body, including the limbs, trunk, and features, are employed in the varied play of thought and passion. Moreover, a deeper examination of the bodily frame has shown that the brain, and the innumerable nervous cords and threads issuing from it to every part of the body, are most intimately and indispensably allied with the workings and processes of the mind, and must, for that reason, have their conformation and structure adapted to the precise nature of those workings and processes. Hence every discovery relating to the structure of the brain and nervous system, as well as in the organs of sense and motion, is likely to be of importance in showing the manner of working of the mind that they are expressly formed to serve. This class of fruitful discoveries has of late years been very extensive, and they promise to be of the highest use in unravelling the complicated scheme of human nature. As one striking example, it has been shown by Sir Charles Bell and others that the nerves ramifying from the brain through the body are of two distinct sets or kinds, although both are often joined in the same bundles; and that the nerves of one of the kinds are exclusively employed in carrying impressions from the organs of sense and the different parts of the body inward to the brain, while the nerves

of the other set are as exclusively employed in carrying influences outward from the brain to the moving and other active organs of the system; the ingoing set being commonly termed nerves of sense, the outgoing nerves of motion. An impression of touch on the fingers is carried to the brain by one nerve, an influence to put the fingers in motion is carried from the brain outward by another nerve; and the same division and distinctness of function are observed everywhere throughout the system. The nervous framework is thus to be regarded as a series of going and returning conveyances between the brain and the different parts of the body; or the mechanical arrangement that has been adopted in connecting the mind with the bodily organs is of a circular kind, like the course of the blood. There is reason to believe that every impression made upon the senses, or anywhere upon the body, and transmitted by the ingoing nerves, has a tendency to excite in the brain an outgoing stimulus to some of the outgoing nerves, which ends in putting in motion some active member of the system. Every act of mind requires not merely a nervous centre, such as some portion of the brain, but a complete circle of brain, nerves, and bodily organs, the round of which is described by the nervous influence at each operation. This must be reckoned the first principle of nervous anatomy in its bearing upon the processes of mind.

The collective recorded experience of mankind, derived from these three leading sources, are the materials bequeathed to us for learning the character and mechanism of the human mind: these materials we have to sift and compare with themselves, and with our own independent observations, until we obtain a rigorous consistency in all our results. Among the indirect helps to the study of mind, in addition to these three great direct sources, are to be reckoned the sciences that treat of the outer world.

#### REFLEX ACTIONS.

There are certain actions performed by men and animals which are so distinctly seen to arise from an outward stimulus reflected back from a centre in the form of a movement, that they have specially received the name of Reflex Actions. This directness of return, however, is not their distinguishing character, but belongs to many actions not so named. What really distinguishes this class of movements, is their being performed unconsciously, or their not passing through what is properly the mental system of the creature. Their effect is the same as some of the mental actions, but they lie without the boundary of the true mental life. Their exposition is, nevertheless, necessary as a preliminary to the study of the proper mental phenomena. The following are some examples of them:—

1. *The act of sucking in infants*, which may be said to commence before the dawn of mind. The contact of the child's lips with the nipple is an impression of touch conveyed inwards by the nerves of the lips to a ganglion in the spine, and causing a returning influence which contracts the ring of the mouth, so as closely to embrace the nipple. This completes one nervous circle, and makes one distinct act; but it is not the only act. The muscular contraction of the lips must be assumed to yield a second sensation quite different from the first, or from the sensation of contact, and capable of setting in operation a second circle. A nerve will have to convey this second or muscular impression to a separate ganglion, whose outgoing threads proceed to a different quarter—namely, to a group of muscles in the back and breast, whose contraction swells out the chest, exactly as is done in the act of drawing in the breath; or we may imagine that the ganglion in question is made to connect with the nerves that ordinarily sustain the act of inspiration. This act of inspiring air, in the present instance, causes a suction at the mouth on pneumatic principles, the nose being made partially close at the same time, and as part of the same reflex act. The inspiration or suction yields a third sensa-

tion, the commencing stimulus of a third circle, which terminates in acting on a new class of muscles. These contract the chest, and force the air through the nose, the impress of which act is the commencement of a repetition of circle second, or of a circle of inspiration and suction; and the two processes of inspiration and expiration thenceforth go on alternately, until they are made to cease by the feeling of satiety. They are, in fact, a reinforcement of the breathing process, coupled with the hold of the nipple by the child's mouth, and the partial stoppage of the nose during the suction. The action is at first purely of the reflex or unconscious kind; but, at a subsequent stage of growth, it is liable to come under the notice and control of the mind.

2. *The act of Swallowing*.—After a morsel of food has been chewed under the influence of a conscious operation, it passes to the back-part of the tongue, and into the bag-like cavity of the pharynx; and by contact with the surface of this cavity, it excites a movement of muscular contraction which forces it down the gullet, and it is carried along the tube of the œsophagus to the stomach. The sensation of contact in each place of the alimentary canal excites a contraction of that place which forces the food to the next; and by a series of reflex actions, it is conveyed through its whole course.

3. *The winking of the eyes* is another reflex action, quite independent of our consciousness. Many of the motions of the lower animals are also reflex, and are to be distinguished from the instincts belonging to these animals, which run through the mental life or consciousness. The motions of insects are in a great measure reflex, the rythmical regulation of them being the only part that is under the cerebral or mental system. Decapitated flies execute movements of their legs, but of an irregular kind, unlike the rythmical and orderly motions that enable them to walk.

In our exposition of the proper phenomena of mind, we shall adopt the following divisions of the subject:—

I. The SENSATIONS, APPETITES, and INSTINCTS, which form an allied group, and make up a region of mind in so far complete in itself.

II. The INTELLECT.

III. The EMOTIONS.

IV. The ACTIVITIES; meaning such as are of a higher order than the Appetites and Instincts treated of in the first division, and which connect themselves with the Intellect and Emotions.

#### SENSATIONS, APPETITES, AND INSTINCTS.

The region of Mind proper is defined or circumscribed by the peculiarity expressed by the term Consciousness, which is an ultimate fact that may be described and distinguished from other facts of body or mind, but which cannot be resolved into anything else. Its leading property is as follows:—

It is the unity, the consolidation, or the centralisation of the operations of mind. Under it all the threads of mental ongoings and movements are reduced to one complex thread, whose course is indivisible. The reflex actions may go on apart and simultaneously, but all that are brought within the sphere of consciousness are rendered mutually dependent, and reduced to act only by turns. The unity of the conscious thread is clenched by the fact, that a large portion of the muscular apparatus of the body is subservient to the operations of the mind; and as no part can be used in two ways at the same instant, it becomes often a matter of necessity that these operations should take their turn instead of acting simultaneously. There being but one great executive apparatus for the consolidated circles of the mind, there can be as it were but one stream of execution, or of movements requiring the use of such apparatus. But the union of many circles in one great conscious circle has the farther effect of making each dependent on all the rest; anything that one is excited to do may be arrested if a stimulus of an opposite tendency happens to have been conveyed to any other

circle. In the sphere of the organized mind, or of consciousness, there is a free communication between the separate centres, which permits of harmony or conflict, mutual assistance or mutual resistance. If a certain motion is given to the arms, and if a motion is also given to the eyes, and if the two are in harmony, the coincidence is felt within the system, and the one sensibly ministers to the support of the other; but if there be any incompatibility, a conflict arises, and one must succumb: such harmonies or conflicts are among the class of feelings resulting from the consolidation of the mind into one thread of conscious operations. The more highly a creature is organized, the more perfect is this union of all the operations of the system into a central train of operations, which enables conflicts to be suppressed at once, and tends to cause the various processes of life to go on in perfect harmony. The sense of vivid mental existence depends on this great peculiarity of united action in one organized train. The fact of consciousness, and the fact of the mutual connection and common understanding of all the more important operations of the system, go together, if they are not one and the same fact. In fine, consciousness is mental existence. The various circles may be going their rounds of operations; but if they impart no feeling, the mind is not awake; the circles are disconnected, and reduced to the mere reflex character. In the state of unconsciousness, any one circle is unable to agitate the whole frame to sympathise with or assist its movements; and in this case the pains and pleasures caused by it are for the time suspended. Such a state as this is exemplified in sleep.

The arrangement we have now described answers to what may be called General Consciousness, as distinct from certain kinds of special consciousness, such as that named reflex attention to one's self, self-consciousness, and the like. The difference is the same as between *seeing* and *looking*, or between the general vision of a wide range of objects and the special or concentrated observation of some single object.

The three groups of *Sensations*, and *Sensational Appetites* and *Instincts*, make the inferior region of the true or conscious mind. They occupy a very prominent, not to say the predominant part of the mental life of the great mass of the inferior animals, and are a very considerable portion of the far more complicated thread of human consciousness. Of the three classes, the *Sensations* are the primary phenomena, and form the starting-point of the other two: an appetite or an instinct must in all cases be preceded or accompanied by a sensation. We shall therefore commence with the Sensations.

SENSATIONS AND ORGANS OF SENSE.

With regard to Sensations in general, it is particularly of importance that we should keep in view the fact, that a complete nervous circle is always described, commencing with an impression on a sensitive surface, and ending for the most part in a muscular action. The overlooking of this great and fundamental property of the nervous system has rendered nearly everything that has been said on the subject of Sensation radically incomplete. A Sensation, when allowed free scope, never fails to go through the entire round already detailed, although, from its being subordinated to the general stream of mind, the latter part of the circle, or the returning stimulus, may be forcibly arrested, or suspended, or turned into another direction; but nevertheless the phenomenon essentially includes the whole course of the completed circle. In describing each class of sensations, we must not merely point out the sensitive surface and the objects acting upon it, but also the returning impulse peculiar to the class, and the muscles or other organs that are concerned in this responsive movement. In so doing, we shall gradually become acquainted with one leading function of the muscular apparatus of the body—namely, its being used to complete the circles of the senses, and to move to and fro the parts of the body where the sensitive surfaces are lodged, in obedience to the ganglionic

stimulus awakened by the impressions of external objects on those surfaces. In general, we may say that an act of Sensation supposes, 1st, A certain object, or influence acting upon the body either from without or within; 2d, A sensitive surface adapted to receive such impressions; 3d, A nerve whose termination ramifies in the sensitive surface, and which proceeds to a central ganglion; 4th, The ganglion itself, which is separate and special for each class of sensations; 5th, The nerve proceeding from the ganglion in the direction of the parts excited; 6th, The muscles moved by such nerves which are usually attached to the solid parts lodging the sensitive surface. In regard to the collateral connections of the circle of Sensation with other circles, there will also exist nervous communications between the ganglion and other ganglia, whose operation may occasionally modify the natural course of the primary circle. Such collateral communications with other circles, and especially with the general current of mind, will have to be occasionally alluded to in the exposition of the Senses in detail.\*

We are commonly said to have five Senses—Sight, Hearing, Touch, Taste, and Smell; but this enumeration is now generally admitted to be incomplete. In our present exposition we shall recognise seven different classes of Sensations, as follows:—

<p><i>Inferior or Animal Sensations.</i></p> <ol style="list-style-type: none"> <li>1. Sensations of Organic Life;</li> <li>2. Sensations of the Alimentary Canal;</li> <li>3. Sensations of Taste;</li> <li>4. Sensations of Smell.</li> </ol>	<p><i>Superior or Intellectual Sensations.</i></p> <ol style="list-style-type: none"> <li>5. Sensations of Touch;</li> <li>6. Sensations of Hearing;</li> <li>7. Sensations of Sight.</li> </ol>
---	--

In this list we have not included the Muscular Feelings, although these are a very distinct class, having very much of the character of Sensations; but our reason for so doing is, that the muscles form an essential part of each sense, and fulfil other functions of a peculiar and distinct kind, which would not be expressed by simply classing them among the senses. They are a wholly unique part of the human system, and must be described by themselves, and not as a member of any group whatsoever. We shall have to allude to the feelings arising from them in the course of our description of the different senses, of each of which they form a part.

The tests of a distinct sense are distinctness of external object, distinctness of organ, and distinctness of internal feeling or consciousness.

1. Sensations of Organic Life.

By these we understand the feelings arising from the operations and processes for sustaining the life and vigour of the system; such as, the assimilation of nutritious matter, the removal of waste, the circulation of the blood, the action of the various secreting and excreting organs and viscera. It is found that the process essential to organic life is the formation of cells, and the building up of all the tissues after the proper fashion of each, which implies the other processes of carrying the proper material to each part, and removing what is superfluous and waste. Bones, joints, muscles, nerves, mucus-membrane, skin, cellular tissue, &c. must be renewed as fast as it is consumed; and the acts both of consumption and renewal, according to the manner that they go on, give rise to a set of feelings or conscious impressions agreeable or otherwise. From all parts of the body there would seem to arise a class of nerves for conveying inward some impression of the general well or ill-being of the animal system for the time. Such impression makes part and parcel of the general consciousness, and of the mental existence and happiness or unhappiness of the individual. It may come equally from the whole frame, or more intensely from some parts than from

\* For a further exposition of the anatomical or physiological character of the subjects treated in the present sheet, the reader is referred to the No. entitled 'Animal Physiology' in Vol. I.

others, in consequence of some peculiar local influences. In the case of a general impression of one even character, pleasurable or painful, the muscular response is seen in the general attitude of the body, which chimes in with the character of the primary stimulus. In one state the body assumes a serene, placid, reposing condition, so as to enable the collective sensation of the system to be more intensely felt; in a different state, the circle is completed by a series of uneasy movements and forced attitudes, as if to evade the feelings of one's own fleshly existence, or to stifle disagreeable impressions. But unless the consciousness be wholly engrossed by some other circles of operations, the well or ill-being of the animal system, as a whole, is sure to be felt in the mind, and to carry out a particular stimulus, and impose a particular expression upon the muscular attitude of the body. Hence all the agents that promote or pervert the healthy action of the system influence the consciousness through this source. Pure air, wholesome nutriment, proper temperature, a congenial electrical state, all affect us through this branch of our sensibility; and all disorders, diseases, lacerations, wounds, perverted or excessive action of the assimilating, secreting, absorbing, or circulating vessels or tissues, influence the mind and the bodily attitude through the same source. When a locality is specially affected, there is a muscular movement imparted to the locality, such as would tend to increase the pleasurable or diminish the painful action. Thus a painful wound in the foot keeps up a stimulus of the muscles attached to it, in the vain endeavour to give it a position such as would ease the suffering; and it is this muscular endeavour that indicates to the mind the direction or locality of any special action of an unusual kind in any part. We are often very much agonized in disorders of the inward viscera, in being unable to direct a muscular movement specially to the part, from its being out of reach of our muscles, but we nevertheless are urged to keep up a stimulus on such as are nearest the disordered region.

Compared with the bulk and massiveness of the entire body, the feelings of its well or ill-being are faint, if we consider how intensely we are affected by such small organs as the ear, the eye, or the nose. It seems intended merely that we should be sufficiently aware of our general state of animal existence, to take an interest in the preservation of our health and vitality, without being wholly engrossed by caring for it. Its sensations enter into the stream of consciousness with a view of requiring the other circles and activities of mind to do what is necessary for the support of life, and for the avoidance of injurious agencies; and we are rewarded by their agreeable character, and by the cheerful cast they throw over our general consciousness, when their indications have been wisely attended to in the provisions made for our healthy subsistence.

#### 2. Sensations of the Alimentary Canal.

It would seem that a special set of nerves is devoted to receiving into the conscious train the states of the stomach and other parts of the alimentary canal, in addition to the nerves which give the sensations of organic life. No other internal organ or viscus affects the mind so powerfully as the stomach.

The sensations are produced by the contact of all kinds of food, and at every stage of its passage through the canal, in the mouth, pharynx, œsophagus, stomach, and bowels. The character of the food in respect of materials and of mechanical consistency determines the character of the feeling; hence the range of feelings is as wide as the range of different alimentary substances, but the distinction between distinct kinds is not always very marked; the great characteristic being, how far it agrees with, or can be readily reduced by, the digestive action of the stomach.

The surface of contact is the mucous surface of the canal, which is covered with glands that secrete liquids to combine with the food. This act of combination or mixture gives forth an influence to the nerves which is

carried to the appropriate central ganglion. This ganglion has not been specifically pointed out by anatomists.

The immediate response of the impression is an action upon the general attitude and position of the body, much in the same way as in the response to the organic sensations. An agreeable stomach-feeling leads us to adopt an easy, resting, relaxed posture, that may permit the digestive action to have its full sweep, and to be fully felt; whereas imperfect or obstructed digestion leads to an irritable, uneasy movement, to quench or suppress the disagreeable sensation.

In the general consciousness the alimentary feelings are very powerful, and communicate a decided cast to the temper of the moment. Scarcely any of the other sensations are so influential on the pleasurable or painful, cheerful or gloomy, turn of the thoughts and emotions. Some of the most horrible states of the system are connected with the stomach—as, for instance, nausea and sea-sickness. So, on the other hand, a good dinner is one of the most gladsome influences of human life. Nature has thus secured a high degree of attention to the proper choice and timing of the matters supplied to the alimentary system.

The Alimentary Sensations are the first steps or primary stimulus of one of the most powerful animal appetites, and of a very large amount of the general aims, purposes, and activity of life both in the lower creatures and in man.

#### 3. Taste.

This is a peculiar sense attached to the portal of the alimentary canal, to be an additional help in discriminating what is proper to be taken as food, and an additional source of enjoyment in connection with the first reception of nutritive material.

The substances used as food are more completely distinguished by the taste than by the feelings of digestion. The tastes of bodies are as widely different as is their chemical composition. But in order to have a taste, a substance must be either liquid or soluble in the mouth. Taste is one of our principal means of discriminating one material from another. There are probably many thousands of different tastes in nature.

The surface of Taste is the tongue and the overhanging palate, which yield a glandular secretion to combine with the substance tasted; and the result of this combination acts upon the gustatory nerves, and is thence conveyed to the gustatory ganglion.

The muscular response completing the round of a sensation of Taste, is directed to the muscles of the mouth, jaws, and throat, and tends either to expel or to receive more completely the substance tasted, according to its character. If agreeable, the matter is kept and conveyed to the stomach, in order that it may be enjoyed to the full. Many substances unsuitable for the alimentary canal are rejected by the ordeal of Taste; but not all unsuitable substances, any more than all substances unsuitable for organic nutrition are rejected by the alimentary feeling of the stomach.

To produce exquisite Tastes is one of the standing endeavours of man, and constitutes the special art of cookery, which, however, is apt to invert the order of real importance of the three classes of wants—of Organic Life, Digestion, and Taste.

The sensations of taste are more distinguishable and clear in the general consciousness than the sensations of digestion, but they have a far weaker influence upon the total temper and enjoyment of the system.

Taste is the foundation of an appetite distinct from the alimentary appetites, although allied with them; but the craving for objects of Taste does not arise within the system in the same periodical and imperious form as the craving for food to the stomach.

#### 4. Smell.

This sense is situated close by the sense of Taste, and often co-operates with it; but properly the sense of Smell is the guardian placed at the portal of the lungs to test the purity of the breathed air.

## THE HUMAN MIND.

The objects of Smell furnished by nature are innumerable. Their essential conditions are to be volatile, and to have an agency of a chemical or some other kind on the liquid secreted from the lining membrane of the nostrils. Solid bodies cannot have a smell unless they possess some volatile ingredient.

The surface of the sense is a membrane lining the complicated cavities, cells, and interior convolutions of the nose, which membrane is very extensive in consequence of this cavernous and convoluted arrangement. It is covered with mucous glands, which yield the liquor that combines with the smelling emanations; the combination producing an impression on the nerves, and these conveying it to the olfactory ganglion situated within the skull above the cavities of the nose.

The returning muscular influence that completes the circle of a sensation of smell, bears upon the breathing action, and upon the opening or closing of the nose. A pleasant smell stimulates an increased inhalation of the breath; a repulsive smell inspires a strong expiration to throw out the offensive matter. Animals have thus a timely warning of what is good or bad for the breathing apparatus.

Smells, like tastes, are very clear and distinguishable, and very delicate tests for discriminating material substances: they are therefore extremely valuable in an intellectual point of view; but their massiveness or influence on the temper or condition of the general consciousness is comparatively small; and only a small portion of human labour is employed in furnishing such of them as may be agreeable.

As giving origin to appetite, smells are more powerful in suggesting tastes and alimentary gratification than on their own account.

In the lower animals, smells are the first step in many appetites, instincts, and actions, which they do not inspire in man. The pursuit of prey, and the desire for the opposite sex, are in many instances initiated by sensations of smell.

### B. Touch.

This we rank as the first of the higher or intellectual senses: it being not merely a knowledge-giving sense, as all the senses are, but a means of forming the higher combinations which are the instrumentality of intellect.

The great difference between the lower and higher senses is, that the sensations of the higher are distinctly recognised as made up of separate parts lying in different directions, and indicating that the object in contact with the surface of sense is spread over space, and has distinguishable portions that may be noticed separately, and lead to a separate muscular response. The feeling of Taste or Smell gives no indication of direction or surface, or of the external position, or even the external existence of its cause: the muscular response can have respect only to the sensitive surface as a whole, there being no discrimination between one portion and another. But in Touch, each separate point sends in its separate sensation, which may bring out a separate muscular response, and a distinct act of attention from the mind at large. The higher sensations have therefore form, shape, and distinctness of parts, and clearly indicate extension in space by requiring the muscular organs of response to travel across the objects from one point to another. Hence in them each nervous thread must have an independent ganglionic centre, and an independent connection with the responding muscles. The lower sensations, on the other hand, are, if we may so speak, shapeless and inarticulate.

The surface of Touch is the skin, which is unequally endowed with sensitiveness; being most sensitive at the tips of the fingers, and on the lips and tongue; and least so in the hollow of the back. The test of this quality is the nearest distance of two distinguishable points. On the hollow of the back, the points of a compass three inches apart give only one sensation: on the tip of the finger, two points distant by a very small fraction of an inch are recognised as distinct.

The kind of action on the touching surface is essen-

tially mechanical pressure, or compression of the parts. This pressure affects the imbedded nervous fibres, and stimulates in them the influence that they carry to the nervous centre of touch. The pressure may be of few points or of many; it may be gentle or heavy, and accompanied more or less with adhesiveness, as in clammy substances: the pattern of the surface or of its pressing-points may be various without end; and lastly, there may be movement or friction in innumerable degrees and modes; from all which we see the sources of the variety of influences, and the consequent variety of possible sensations.

The ganglion or central seat of Touch has not been completely ascertained, but has been conjectured to be a certain portion of the base of the brain called by anatomists the *Thalamus Opticus*.

The out-going nerves lead to the muscles of the organ touched, and the usual responsive action is to grasp the object in contact; or if it be of a repulsive kind, to relax the grasp, and withdraw from it.

The qualities of body made known by Touch are such as hardness, roughness, solidity; and in combination with the muscular movements that complete the nervous circle, it gives us the sensations of extent of surface, size, and shape. Each muscular position assumed by the touching organs gives a distinct feeling, and a series of muscular positions makes up one characteristic complex feeling. The muscular part of this sense also gives the feelings of force, strength, and resistance, as well as of physical contact.

The sensations of Touch are the starting-points, and the source of guidance to a large proportion of bodily movements, instructive, habitual, and voluntary, as in many of the manual and mechanical operations.

In the current of the general consciousness, these sensations are of great importance.

### Sensations of Heat.

These are so very distinct and peculiar, that they have been sometimes considered as an independent class: but there are reasons for believing that they are only a variety of Touch. They are felt by the surface appropriated to Touch, and conveyed by the touching nerves; and the chief action of heat on any body is the mechanical effect of expansion; or its opposite, contraction. None of the ordinary sensations of Touch, however, give so powerful a feeling or so energetic a stimulus as heat. The response to an agreeable warmth is to keep up the exposure of the part heated.

Heat and cold in the internal parts of the body become mixed in their effect with the organic feelings and processes, on which they have a very powerful influence. The formation of new cells, the oxidation of the tissues, the secretions and excretions, are all stimulated and controlled by temperature, and the sensation of temperature comes to be felt through these. On the whole, in proportion to the influence of heat on the system, is the effect of the feeling it gives on the general consciousness, and the craving or appetite founded upon it; and likewise the exertions of human life that are set agoing on its account.

The feeling of warmth combines, with the other sensations of Touch, in discriminating the surfaces of bodies and their qualities.

### Sensations of Hearing.

This sense is more special and local than Touch, but agrees with it in being a mechanical sense, as distinguished from the chemical senses of Taste and Smell.

The action in the case of hearing is a very refined case of touch, being the pressure of a liquid on an expanded membrane of great delicacy, into which the nerves of hearing ramify.

The ear consists of three cavities: the outer cavity is open to the air and closed within by a tight membrane, or drumhead, which is the outer wall of the second or middle cavity: in this middle cavity is contained a crooked line of connected bones, one end of the line being lodged in the drum, and the other end on a hole

in the inmost cavity, called the labyrinth. The labyrinth is filled with liquid, and contains an irregular structure of bone described as consisting of a cockleshell, and three semicircular canals; on the inner surface of these bones the nerves are spread out. The vibrations of sound strike the drum of the ear; the movements of the drum are communicated to the bones of the middle ear, and by them communicated as vibrations to the liquid of the inner ear, which presses on the nerve surface with more or less force, according as it is acted on by the bone in contact with it.

The impressions are carried in to an auditory ganglion, and the responsive movements are made by means of four muscles attached to the bones of the middle ear, whose action either tightens or slackens the drumhead or membrane: when a sound is agreeable, the membrane is tightened to receive it more distinctly; when disagreeable, the opposite happens, according to the usual law of the responsive action of the senses.

The sensations of Sound differ according to the character of the vibrations producing them, and these, again, according to the character of the sounding body, whose nature is thus discriminated by the sensations to which it gives birth. The vibrations may be strong or weak, rapid or slow (which is the chief distinction of musical sounds), regular or irregular, in a single or in many streams, and of a character varying with the substance producing them, which enables us to tell whether a sound proceeds from wood, stone, metal, &c. The liquid of the inner ear takes on a different movement and pressure from all these differences. Moreover, by means of the muscular part of the ear, we are made aware of the direction of the sound in a rough, and not very accurate way: the responsive action tends to stretch the drum in opposition to the source of the sound. The muscles are also affected by the greater or less strength of the sound, and by its variations of force, which require in them a variation of the adjustment. Moreover, the volume or expanse of sound has an effect on the muscular sensations of the organ, by causing a kind of broad sweep to be given to the directing bones, to take in the entire compass of the action. This broad sweep is in hearing, as in sight, the cause of a very powerful sensation: the roaring of the sea, the reverberations of thunder, and the firing of artillery, are examples of the objects that bring it into action.

The sensations of Sound are as numerous as the character, forms, sizes, and circumstances of sounding bodies, and are the medium of a very large amount of our knowledge of external things. They are the source of a vast extent of pleasure when wrought into music; and in the art of speech they exercise a very wide and manifold influence on the intercourse of men, and on the operations of the human mind.

As in Touch, the sensations of Hearing are resolvable into distinguishable portions, or have form and shape. They are also the starting-points of innumerable other circles of mind—instinctive, habitual, voluntary, intellectual, and emotional.

#### 7. Sight.

This is undoubtedly the highest, most refined, and most perfect of the senses. The agent concerned in it, Light, is the subtlest and most exquisite power in nature: it has no mechanical momentum, but it seems to have the power of operating a very delicate class of changes upon material bodies, which changes are known to us only through itself, as in the processes of copying objects by the solar ray. The precise action of light on the surface of sense in the eye, cannot in the present state of our knowledge be described.

The surface of Sight is most probably the black screen in the back of the eye which we see shining through the hole of the pupil; on this black screen the nerve is spread out, to be affected by whatever changes light causes in the absorbent black surface.

The impressions are conveyed by a thick nervous cord to the optic lobes of the brain, and the immediate

response is directed to the six muscles that move the eyeball, and turn it on every side to face the quarter of the rays of light. These muscles have the usual function of tightening up and adapting the organ to confront agreeable radiation; while for disagreeable sensations there is the additional apparatus of the eyelids, which, by a reflex action, screen the eye from a painful impression. The eyeball itself is essentially an optic lens. (See Nos. 8 and 16.)

The sensations of Sight correspond with the infinitely various character of luminous emanations, as determined by the surfaces they come from. The sun's light falling on bodies is reflected from each in a modified form dependent on the texture of the surface, and the sensations resulting are to us one means of distinguishing surfaces. The recognised varieties of light, as ascertained by our sensations, are chiefly intensity and colour, both of which are subject to innumerable shades of difference, according to the variety of the material substances presented by nature.

The muscular portion of the eye gives the sense of direction more accurately and decidedly than either hearing or touch. The adjustment of the eye to points of objects (the discrimination of which is exceedingly close) by the muscles, yields a most accurate estimate of their direction, such as the other moving organs can proceed upon in making for such points. The change of the ball from confronting one point to fixing it on another, gives the feeling of length in space; and the traversing of an area in all directions gives the muscular feeling of surface and expansion. There are certain muscular adjustments adapted to the distance of the object, and from these arise the feeling of distance from the eye; and when this is combined with the former, we have the feeling of cubical space. When the colours and shades of bodies unite their sensations with the muscular feelings of expanse and distance, we derive the feelings and notions of solid bodies. Professor Wheatstone has shown that the impression of solid shapes results more particularly from the combined images of the two eyes, which, as it were, take a grasp of an object by two faces, and thereby become sensible of its cubical form.

The pleasures of Sight are numerous and intense, and many of the fine arts have reference to them alone. Its share in the intellectual functions, and in the guidance of human life, predominates over all the other senses. Its impressions are more durable and more easily revived after the object has disappeared than in the case of any other class of impressions, and hence their importance to the intellect, which deals largely in the shades or remnants of departed sensations.

#### Muscular Feelings.

Muscularity being not a sense, but a portion of the circle of each of the proper senses, its peculiar feelings must, as we have seen, enter into all sensations. We shall now allude to these feelings apart from their connections with the senses. The muscular system is the essential instrument of all thought, emotion, and activity, and the great link of connection between any one nervous circle and another.

The muscles are subject to many states. They may be tense or relaxed; they may move rapidly or slowly, continuously or interruptedly, rhythmically or irregularly; and each state has its own separate feelings. They also yield great differences of feeling according to the degree of vigour or weariness that may belong to them. As they constitute a very large mass of the human system, their mere animal changes of nutrition, exercise, and exhaustion, give forth strong impressions to the general consciousness. In this respect muscular states have nearly as great an influence as alimentary states.

There is an extensive adaptation of the machinery and arrangements of life for the express object of meeting the wants and capacities of the muscular system—such as furniture, carriages, walks, sports, gymnastics, &c. It is needless to add that it is our only means of acting mechanically on the external world.

The prominent feelings and notions derived from it are those of *force, power, might, energy, or resistance*: also the feeling of motion as a property of matter, of space as the field for motion, and of time as marked out by motion through space. All these feelings the muscular system contributes to our three higher senses—Touch, Hearing, and Sight.

When a sensation is followed up by an instinctive or other action, the muscular part of the sensation yields the impression that wakens up the action: or a muscular sensation is the link between one act and another everywhere throughout the system.

#### APPETITES.

These are peculiar and distinct states of mind allied to the Sensations, but involving in addition some of the other active circles. When a sensation is of that uneasy character that is not satisfied by the proper muscular response, but maintains in the general consciousness an irritable unresting state, so as not to allow the mind to go on calmly, unless something has first been done for the relief of the locality affected, the action is called an Appetite or craving. Such cravings generally imply that there is a want or deficiency in the part they arise from.

The animal system works to a great extent on the principle of alternation of states. Each organ usually passes through successive conditions—such as nutrition, exercise, and repose—and it manifests a craving for each in their turn: if this craving is gratified immediately, appetite is swallowed up in satisfaction or contentment; if not, the general consciousness is disagreeably acted on by the irritation of the neglected organ, and the powers of body and mind are, as it were, importuned till the want is allayed.

Each class of sensations contains among its number sensations of appetite; indeed the whole of the so-called disagreeable sensations may be considered of this kind. The sensations of organic life become cravings when the system is not in good working order, or is refused its proper alternations of treatment. Thirst is perhaps one of the most intense of this class. The wants of digestion yield the well-known appetite of hunger: it and thirst being the most powerful cravings of the system. Taste and smell do not readily yield appetites that are the consequences of wants periodically growing up in the organs; but when they are roused by an agreeable contact, they put forth a craving for its continuance up to the point of satiety. There are many other appetites that are only roused by a present stimulus, it being with them 'out of sight out of mind.' The appetite of sex originates within the body like hunger, but its strength of craving depends very much on the presence of external stimuli; and hunger itself may be increased by such means, as in the presence of an abundant and dainty meal. The appetites of the muscular sense, which are alternately for exercise, rest, and nutrition, are next in strength to hunger. The appetite for sleep arises within the nervous and muscular system. The higher senses have but moderate cravings, these being chiefly for the alternation of stimulus and rest: the eye, when fresh and strong, craves for light, and the ear desires sounds; when wearied, they seek to be withdrawn from such influences.

When a diseased state comes over any of the organs, the craving thence arising differs from ordinary appetites in not suggesting the means of relief. But this difference is only apparent, for the appetites do not generally of themselves point out what is required to satisfy them; either experience, instruction, or a special instinct is needed for this purpose; the exceptions are such cases as sleep, and the cravings for activity and repose.

The Appetites are largely involved in human enjoyment, and are stimuli to human thought and activity. In proportion to their strength, the frequency of their recurrence, and their capacity of being gratified, is their influence on the general stream of consciousness. The Desires (subsequently treated) differ from the Appetites only in bringing the intellect more fully into play.

#### INSTINCTS.

These belong to the special means of action that each animal possesses for accomplishing its various works, and fulfilling the ends of its existence. They are the untaught activities and capacities of the animal nature.

When we keep out of view the reflex actions, which have been commonly classed with instincts, the instincts in man are such as these:—

First, A large class are referable to the tendency of the system at large to accord or fall in with the state of any one part. A sudden stroke of pain produces first by a reflex movement, or rather by the natural course and completion of a sensational circle, a retraction of the injured part; and next a general commotion of the body at large, a cry of agony, and a general convulsion of limb and feature. This extension of the attitude of a part to the whole is to be called instinctive, and it is effected under a general law of the muscular and mental system, by which there is a constant tendency to unity of position and state over the whole. Rapid movements of the limbs produce like movements in the exclamations, looks, features, gestures, and even in the very thinking processes. By this principle it is that the body follows the lead of the eyes in walking or taking an aim.

Walking may be reckoned an instinctive action, although it takes a little practice to be perfect in it. The motion that it involves—namely, an alternate swing of the legs—is natural and spontaneous from the earliest period of infant life. This exemplifies another general property of the muscular and nervous system, which is the principle of *alternate motions*. The members that are in pairs tend to move by turns in consequence of an express organisation suited to that effect. The eyes are an exception to this law. A third character of the muscular constitution is the power of *vermicular motion*, or the tendency, where there is a succession of members, for a movement to pass from one to another through the whole system. The progressive motion of worms, and the action of the alimentary canal, take place under this principle; but it also acts in the progression of quadrupeds, and in the climbing action of man and other animals.

But the most strongly-marked description of instincts are such as seem to proceed upon an innate knowledge of what is usually learnt by experience alone. This is exemplified in the action of the senses of taste and smell, when they enable us to decide upon what is good for the alimentary canal in the first place, and for the organic system in the second place, as in the choice and rejection of food. A still more surprising anticipation is in such a case as when an aquatic bird knows water by the sight before it has ever been in it. The migrations of birds show the same characteristic of preordained knowledge: a certain sensation tells them which is the direction of the warm regions of the earth, just as men know it by the mid-day sun, or by a weathercock. Many animals are supposed to excel the human species in their pre-established connection between the sensations of smell and taste and the wholesomeness of the food of which they should partake.

The elaborate constructiveness of many animals—such as the bee, the beaver, and the nest-building birds—is a still higher stretch of instinctive or preordained power; although probably, when better studied, these operations will come under simple laws, such as have been alluded to above.

A circle of Instinct is usually secondary, or in succession to a circle of Sensation. The muscular feeling that terminates a sensation is the first step in an instinctive circle; and if there be several successive movements, the feeling of the last muscular position in one movement is made to stimulate the ganglion which sets on the second. Thus, in walking, the feeling coming from the muscles of the right leg, at its full forward position, is conveyed to the ganglion that sends out the stimulus to the progressive muscles of the left leg, which is moved forward accordingly.

## CHAMBERS'S INFORMATION FOR THE PEOPLE.

There are certain of our judgments and beliefs that are usually considered as instinctive; but, these require to be taken up subsequently among a higher class of Activities. We here close the group of Sensations, and their allied Appetites and Instincts.

### THE INTELLECT.

The products arising from the action of the powers of the Intellect upon the Sensations, Appetites, and Instincts, or upon the more simple circles of mind, are very numerous and varied, and might be exemplified by all the arts, sciences, and organisation of human life, and by what is meant by such terms as Understanding, Reason, Judgment, Abstraction, Memory, Imagination, Invention, and the like.

The first property or law of mind upon which Intellect is based, is a property that seems to adhere to the inferior circles as such, and therefore we do not state it as one of the laws of Intellect proper. It is the law of the permanency, endurance, and coherence of sensational states. When a surface of sense is impressed by an object, and the influence transmitted to the central ganglion, from which the responsive action proceeds outward to the connected muscles, we find that the impression once made continues for some time more or less after the object is withdrawn; the sensitive surface, the nerves, the ganglia, and the muscles, all retain for a short period the state which they have once been made to assume; or the circulation of influence perseveres in the absence of what set it on. We find also that the effect of each stimulus is to leave behind it on the circle a certain bent or susceptibility to the same stimulus at another time. If the same sensation be repeated, the sensitive surface will take it on more readily, the nerve will convey it with more alacrity, and the responsive muscles will be found more vigorous and alert in the execution of their function. This is one of nature's laws of the growth and development of our capacities of sensation and instinctive action: it is the principle that enables us to acquire a command of our senses and instinctive movements; the efforts of attention by the eye or the ear, and the alternate movement of the limbs, although provided for by the original organisation, are not perfect until they have been familiarised by practice and repetition with the operations that have to be gone through. The law in question is therefore one of nature's regulations for the growth and maturity of the system; and it continues through life, although most vigorous in its workings during early years. It might be called the Law of Sensational growth.

The laws of Intellect proper make a very decided advance beyond this. Instead of simply hardening or confirming the current of each sensation in its own circle, they bind separate sensations to each other, and build up complicated masses of sensation and activity, which may not merely be more easily revived by the repetition of the first impressions, but which may be revived without employing the original in any shape, so that we may live in a world of the most varied sensation while none of the objects of sensation act upon us at all, and may be affected by impressions recovered from the repositories of the mind more powerfully than by any action direct from nature without.

The First Law of Intellect, properly so called, has been termed by psychologists

### THE LAW OF CONTIGUITY.

Two or more sensations, impressions, actions, or states of feeling, existing together or in close succession, tend to cohere, so that the future occurrence of any one of them is sufficient to restore or revive the others.

As we have at least seven senses, and as each of these may be stimulated by a successive stream of distinct sensations, and as we have also appetites and instincts, besides higher emotions and activities, and since we are ever in the presence of a world that sheds innumerable influences upon these varied suscepti-

lities, it is obvious that the stream of general consciousness, or of the waking mind, must be a highly-complicated train of movements. In this state of things the law of contiguity comes into play, and determines that the impressions, feelings, and movements that have run together for a certain length of time, or have been repeated sufficiently often, shall so cohere, that when one is roused by its outward or inward object, the others shall be manifested along with it, independently of their original stimulus. If we take, for example, a concurrence of two sensations, one of sound, and the other of sight, as the sound and the sight of rushing water—after a sufficient length of time the two impressions so grow together, and are so cemented by an operation going on within the mind, that the one may at any time recall the other: if we hear the noise while the object is concealed, the visible picture starts up nearly as if we were looking at the reality. The law of contiguity develops, as it were, within the mind a power of bringing before it the same impressions as are ordinarily given by the agents without. We may thus have visible pictures, and audible and tangible impressions, and their completed circles, without the presence of sights, sounds, or contacts; and these impressions may be the first link in raising into action subsequent circles of appetite, instinct, or other activity, thought, or emotion. We shall now briefly state a few of the general results of this law; to develop them fully would far exceed our limits:—

1. The impressions of natural objects (which generally excite several senses at once) are compacted into wholes. Thus many things in nature may affect sight, hearing, touch, taste, and smell, and, it may be, the alimentary and organic feelings in addition; and by repeatedly experiencing these conjoined impressions, we come to form a complex impression or aggregate notion of the entire object. Thus our mental impression, what we call our idea or knowledge, of an orange, is an aggregate impression of this sort cemented by the force of contiguous association.

Many impressions that we are apt to reckon as single or simple sensations, have, in fact, been compounded by this associating force. Thus our impression of the round aspect of an orange is a complex impression of sight and muscularity; the visible picture being an aggregate of visible points, and the expanse and roundness being the result of the repeated sweep of the eyeballs over its area, which result is itself a complicated tracing of muscular sensations; and the combination of these with the visible aggregate makes the total impression of visible form.

Many natural objects, such as the human body, are permanently made up of a great many parts, each requiring separate acts of attention, and yielding separate sensations. The fixing of these altogether in one total impression is the effect of contiguity.

2. Besides the conjunction of parts in the same object, we also find that nature has in many cases coupled distinct objects together by some of those powers of distant influence which prevail in the world. Thus a warm latitude is coupled with rich vegetation, and a sea-coast with a moist and temperate character of climate. The tides coincide with the positions of the moon, and the migrations of birds with the changes of the seasons. These conjunctions are laws or ordinances of nature, and become impressed on the human mind by the association of contiguity.

3. The accidental juxtapositions that occur around us, or those conjunctions that may happen from any cause, and that continue in virtue of the inertness of matter, impress themselves in the same way. Thus it is that we carry about with us the picture and arrangement of our own homes, and of the localities where we have often been; we associate house with house, and street with street, and have in our minds a connected view of each prospect, large or small, that has been frequently before us. In short, all the fixed arrangements around us, and the local and geographical aggregates with which we have become conversant, become

permanently fixed in our conceptions, exactly as they stand in nature.

4. The whole class of regularly-recurring successions, including cause and effect, as the most invariable of all successions, are stamped in the mind by the same force.

5. The addition of names to objects for the conveniences of intercommunication and reference, is rendered permanent by the operation of contiguity. After a certain number of repetitions of the word 'moon,' while attention is fixed on the object, the two impressions come to cohere, and are thenceforth able mutually to recall each other. The acquisition both of our mother tongue and of foreign languages is therefore a consequence of this adhesive force. In like manner the fixing of connected series of words—that is, of narrations, statements, assertions, and literary compositions—what is usually called 'a verbal memory,' depends on the same law.

6. All the steps of a connected procedure in the arts, professions, and occupations of life, are joined together after the proper degree of repetition, under this associating principle; and many other examples might be given. The time or the number of repetitions necessary for a full adhesion to take place, depends on the power of adhesiveness peculiar to each individual, and on the freshness and freedom from distraction of the mind at the time, as well as on the impressiveness of the objects. The force of contiguity is most energetic in early life, and seems identified with the vigour of growth of the system. It may be called the Law of Intellectual growth, since we have called the fixing of Sensations and Instincts the force of sensational growth.

LAW OF SIMILARITY.

Any present impression or state of mind tends to revive previous impressions that resemble it.

This law takes a very different sweep from the preceding. If the operation of contiguity has formed in the mind some great aggregate impression that has a distinct character and form, and if at any future time a new impression is made resembling it in one or more points, there is a tendency for the present to revive the past, and for both to flash together into one, so that the new image will receive all the particulars that the old can add to it, and will be saved the trouble of acquiring these afresh. If we suppose a person to see a ship for the first time, and to examine minutely all the peculiarities of its structure, within and without, and to dwell upon them so long that the aggregate picture of the ship clings together in his head, and can be revived entire when any part is brought before his view; and if after this he observe at a distance the outward form of a second ship, this by similarity will recall the already-formed picture of the first with all its details; and without having the means of fully examining the second, he can transfer to it at once the particulars of the other, and thus supply a knowledge of what is hidden from the eye. As nature has produced many repetitions of the same objects and forms, it is a vast economy of human labour to be able to know an entire class through a single individual thoroughly studied; and the application of what is known and conceived of one thing to all others like it, is effected through the power we are now considering. When objects are not perfectly identical, we have still the advantage of the similarity as far as it goes; and for each new individual, we need only to learn what is its difference from some one previously known, in order to possess a full acquaintance with it. We shall now adduce a few examples of this law:—

1. The extension of old sensations to new objects. We have seen that it is a work of time and growth to acquire the engrained sensation or aggregate notion of any one natural object—such as an orange, a tree, a house, a man. The mere round form of an orange requires a considerable amount of muscular experience often repeated; but when this form has been completely mastered, it is then easy to acquire the notion of the round form of any other round object. Being once exer-

cised in the notion of roundness on some one individual case, we find it easy to fall into the impression in any other case: the old state is set on by the new contact. So with any other form, as of a tree, or of a plan of a country, or with any other sensation whatsoever. No matter although the already-acquired sensation is accompanied in the new instances with a different class of other sensations in the aggregate picture; it is the peculiarity of this intellectual force to break through unlike accompaniments, and still make like flow to like. The exercise of acquiring the sensation of roundness from an orange will serve us in acquiring the impression of an apple, or a plum, or a cannon-ball; and for each new case the labour of attention will be needed only for the new circumstances of colour, size, and modifications of the round form. So in the case of hearing: when the ear has been repeatedly exercised in a set of sounds, as in the words of a language or the notes of an instrument, it falls into or recognises them again under new combinations, as when repeated by a different voice or instrument.

2. The word *identification* expresses a large class of the operations of similarity. We identify a portrait with its original, the common features in a family, the sameness in character in the scenery of a country or in the aspect of a population, the institutions of different nations, the events of remote ages, the characters of different individuals—all by the force of this law. There are great inequalities in men's powers in this respect: in some, the differences in a few of the particulars serve completely to obstruct the perception of similarity, so that in many instances no recognition of the past in the present takes place, even though a real likeness obtains between them. An incapacity in tracing likenesses on this principle is the very essence of intellectual imbecility and weakness; and on the other hand, a high facility in recovering all past impressions that contain anything in common with some present impression, is the main foundation of all high intellectual power, capacity, originality, invention, and genius. The peculiar species of the capacity will depend on the other points of character; but the main absolute force of it resides in the perception of likenesses, and the revival of the past by the force of similarity. To the extent that we are unable to bring up past acquisitions of mind to serve present emergencies, we lose all the advantages of nature's repeating herself in many circumstances, and have to undergo fresh labour for every individual case.

The identification of the identical phenomena of nature often demands an intense power of similarity, owing to the repulsion of unlike circumstances. Thus the man that identified the attachment of the moon to the earth with the fall of a stone, will be reckoned through all time to have been a very extraordinary genius; ordinary minds would not have traced anything common in appearances which to the superficial eye are so utterly unlike. The identification of lightning with the spark of an electrical machine is another example of the same uncommon force of intellectual perception. Thus the inductions and generalisations of science are in the main the consequence of great stretches of the power of similarity.

3. In literary efforts there is abundant scope for tracing the operations of the same power. A great part of the formation and growth of language lies in applying old names and expressions to new objects, in consequence of a felt identity or likeness between the things. Thus the word 'head,' primarily applying to a part of the human frame, has come to be used in reference to innumerable other things quite different, but having all some one feature in common with the human head; as the 'head of a house,' the 'head of a mob,' the 'heads of a discourse.' The great class of expressions called 'metaphors' are struck out on the same principle, and are produced most abundantly by the men that possess an intense power of bringing together like in the midst of unlike.

4. The tracing out of unity, consistency, harmony,

and uniformity, in a mass of varied things and circumstances, is a direct effort of similarity.

5. The application of general laws and rules to individual cases, and deductive reasoning, in general demands the same effort: it is only in virtue of similarity of subject that a law or rule can be transferred from one case to another.

In every high operation of intellect and genius this power is requisite. Contiguity leads to routine, and to the arranging of things as they happen to be in nature by mere juxtaposition; similarity breaks through juxtaposition, and brings together like objects from all quarters. It is by far the grandest manifestation of the human mind; it enables us to rise to the unity, simplicity, and comprehensiveness of plan that regulates the complicity of the world's arrangements and movements, and lessens to an unlimited degree the toil attendant on man's situation in the universe.

LAW OF COMPOUND ASSOCIATION.

Impressions, notions, or thoughts, may be recalled more easily by being associated with two or more impressions or objects present to the mind at the time, whether by contiguity or similarity.

The two forces of contiguity and similarity express all the powers that nature appears to employ in maintaining the operations of the human intellect; but there are certain peculiar cases of their working that deserve to be specified as separate, although dependent laws. One of these is the case now supposed. When there are present to our minds two impressions, ideas, or pictures, each associated, either by contiguity or similarity, with some third state that is past and out of mind at the time, the compound action is more effective than either action by itself; that is, the separate bonds might be too weak to revive the past object, but acting together they succeed.

A common example is furnished by such a case as our endeavouring to remember something said or done on some past occasion, whose other circumstances are distinctly before us. The bond of contiguity not having been strong enough to connect the remembered circumstances with what is sought, we fail in the attempt; but should anything cross our minds having some slight resemblance to the matter in question (perhaps too slight to have revived it of itself), the faint contiguity, joined to the faint similarity, effects the revival of the recollection that we were struggling for. So two contiguities or two similarities will always be more powerful than one. Names that we have both read and heard, or that have been associated both with a book and a speaker, are most easily revived when both book and speaker are in our view. A complex scene may be revived effectually if there are present to us several representatives or resemblances to it in several aspects.

LAW OF CONSTRUCTIVE ASSOCIATION.

The mind has the power, by means of association, to form or construct aggregate impressions of things, exactly as if they were derived directly from the outer world acting through the senses.

We have hitherto referred to the revival of past impressions of objects, exactly as they were formed by the action of the originals on the senses and intellect; but this does not exhaust the range of the intellect's powers. It is possible to form a picture of what has never been experienced, to all intents and purposes the same as the pictures of actual experience; and the effecting of this is what we denominate 'constructive association.' To take a simple example:—

Suppose we see a building formed of brick, and desire to judge the effect which it would have if composed of marble, we require to construct a new conception, where form and outline shall be derived from what is before us, and substance and colour from our notions of marble. The effort is one coming under the class we are now considering, and is within the power of an ordinary intellect. A still more easy effort, however, would be to conceive a known building

transferred from its actual site to some other site, also clearly conceived, and to form the complex conception of the scene so composed. By a little exertion, we could impress on our minds the picture of the supposed combination exactly as if it had been a real scene that we had long and familiarly known. The power of contiguity would suffice to make a coalescence of the imagined ingredients as well as of actual combinations. Such instances of the mere addition or substitution of a new ingredient in an aggregate found in actual life, are among the simplest and easiest efforts of the faculty in question.

The difficulty of the process increases with the complexity of the combination. Should we desire to realise to ourselves a town on the site of London, with the streets planned on a different scheme, such as that proposed by Sir Christopher Wren, and the houses all built of red sandstone, and the inhabitants dressed in the Oriental costume, we should find a prolonged and energetic effort necessary; and very few people would ever succeed in realising the combination with the same clearness and steadiness as if they had actually lived for some time in a place so made up. It is, nevertheless, within the power of the human mind to do so. By conceiving as vividly as one is able each of the particulars in turn, and by going over the whole again and again, they would at last aggregate themselves into a single whole, which might be retained and repeated in the view till it held together as a coherent picture. Such an exercise is perhaps one of the rarest that is ever attempted by the mass of mankind, who have in general no adequate estimate of the amount of undeveloped capacity lying in human nature.

One of the commonest classes of cases under this law, is the case when some object in nature is represented by one of the imitative arts, and when we resolve the representation into a reality by adding from our experience of realities what is deficient. Thus if we endeavour from a dead statue to conceive a living man, we must endeavour to bring together the conception of the statue and the conception of true flesh, and of the actual colour and aspect of life, and maintain the two conceptions in our view till they fall into one, and become to us the picture of a living human being having the shape and expression of the statue. This would be reckoned an exceedingly difficult effort—the difficulty arising partly from feebleness of faculty, and partly from want of exercise and cultivation. Men of superior minds, or who have made this a study, would perform the operation with ease.

To realise a person or scene from a painting is an effort of the same intrinsic character. We require to keep in view some real scene in order to acquire the expanse and the colours of a reality, and to take along with this the form and outline given in the picture, till the two are fused, if we may so speak, together, or till the scene represented in the picture is the same to us as if we stood before the reality.

This faculty enters into all the higher operations of mind. It is the direct basis of Imagination, and is requisite in Reasoning, Abstraction, and in every kind of originality. It represents the highest range and consummation of the human intellect.

THE EMOTIONS.

The Emotions are a class of feelings in their nature analogous to the Sensations, but differing from these in being mixed up and associated with intellectual operations. They might be not inaptly defined as Intellectualised Sensations.

There is not the same anatomical distinction among the Emotions as among the Senses, nor can they be classified solely by a reference to the structure of the human frame. Several of them have a very specific local apparatus, such as Tenderness, and the emotion of the Ludicrous; but as respects many others, we must, in arranging them, refer to the objects of the outer world that set them in action. Man is not fitted up so

much with certain particular emotions, as with a large capacity of emotion; and according as he is acted on by the things about him will his emotions show themselves. New circumstances and large changes in the constitution of human society develop new feelings of interest and new trains of emotion. The unfolding of the mysteries of nature produces a class of feelings unknown to ignorant ages; but the men of these ages were in their turn affected with a species of wonder and awe, which disappeared before the growth of the scientific analysis of the world. The emotions produced in the mind of one that can look back over a vast series of historical revolutions, could not, in their faintest germ, be traced in a denizen of primitive society. So all the new works of men, and all the great changes that come over the peopled earth, give birth to original and appropriate emotions, which bear a part in giving an interest and a charm to human existence. Likewise each variety of condition, rank, and occupation, has its own form of stirring the human breast, and its peculiar resources against the cold, dull, empty, blank condition of mind that is reckoned one of the greatest miseries of existence. Emotion, in the practical point of view, is the opposite of ennui.

Adopting the order of arrangement which seems to us on the whole the most convenient in a brief sketch like the present, we shall commence with

THE EMOTION OF TERROR.

The feeling of Terror, in its most simple form, is an instinctive tremor communicated to the system in consequence of some sensations, that, while being disagreeable, are new, strange, or unwonted. Objects that have the aspect of might or power acting in an entirely new form, and suggesting destruction or danger without indicating where, how, or when, disarming resistance by uncertainty, and giving no sign as to what should be the proper response of the system to their approach, are said to be objects of Terror, trembling, or alarm. The physical action of shaking or quaking seems to be the result of the breach that arises in the nervous circuit, as when a sensation is conveyed inwards which is incapable of rousing some one distinct stimulus to the responsive muscles outwards, or which suggests two or three at the same time, that paralyse each other, and lead to none being issued. This state of things seems constantly to produce a quaking agitation of the whole frame, with an unsettling of the tone of the system, and a very great discharge of nervous energy, which paralyse and weakens all the powers of life. A visible blow may require all the force of the system to meet it; but if the response or mode of resistance be distinct and clear, it does not paralyse and debilitate the living energies. The uncertainty which is the cause of Terror is the opposite of knowledge, experience, and familiarity, or of the full intellectual recognition of the whole train of circumstances attached to each event. Terror, therefore, is to be met by knowledge.

To early life and inexperienced minds, many of the objects of nature are the cause of Terror. Children are dismayed by strange faces and strange dwellings. Rude nations are terrified by eclipses, comets, earthquakes, and rare appearances, and only extricate themselves by imagining some connections between them and the powers above, which give them a meaning and purpose. The pestilence walking in darkness is an object of universal Terror; it becomes disarmed, according as we are able to see the fixed laws and conditions of its working. A government that acts without the medium of law is a reign of Terror; confidence is produced by adherence to known rule. Aillments which we have formerly gone through are looked upon with indifference; but any symptoms of disorder not experienced before put us in a state of alarm. Uncertainty is always a cause of disorganisation of the whole plan of human life. Prudence and morality are supported by a clear perception of the consequences of our actions, and of all that is likely to come upon us. It takes only a very small matter to induce a state of Terror; but as

in the kindling of a fire, or the bursting of a flood-gate, the evil consequences may be a thousandfold more extensive than the cause. The minor instances of this emotion are seen in the bashfulness, shyness, and reluctance that are felt in entering upon new occupations, or coming before new people or strange assemblages. There is a considerable waste of nerve incurred on all such occasions. Terror is the noxious ingredient in superstition of all kinds, being the natural result of the ignorance and uncertainty that superstition grows upon. Fear is only a variety of Terror, having in it somewhat of the anticipation of certain evil; and as we are rarely prepared to meet an evil event so as completely to disarm it of its pangs, a certain amount of Terror is inspired by the anticipation.

When mixed up with many other feelings of a different description, Terror is sometimes reckoned an agreeable stimulus; as in poetic and dramatic compositions, legendary tales, and superstitious rites. It is then diluted to the degree of throwing an interesting excitement around matter that might otherwise be felt as dull and insipid.

The emotions of Wonder, Surprise, and Astonishment might be classed next to Terror, as having a certain degree of affinity, although so far distinct as not to be included under it. Their object or exciting cause is some breach of expectation, or something occurring where a very different thing was looked for. Experience leads us to adopt certain views as to the usual course and arrangement of affairs and events, and when they turn out in contradiction to our preconceived notions, we are affected with a kind of shock or excitement that is called 'Surprise.' When a thing very much surpasses in kind or degree the notion we had formed of it, or disappoints our expectation to a great and unaccountable extent, we 'wonder,' and are 'astonished' at the event. This feeling, therefore, so far agrees with Terror, that it has reference to our previous knowledge, and to its being nonplussed by actual occurrences; but it does not imply, in ordinary cases, that we are unable to give a distinct response to the appearance, or that we fall into the tremors of painful uncertainty. In a world so complicated and so hard to predict, Surprise often overtakes us, and may be accounted one of the standing emotions of human life. Being an excitement of a not disagreeable kind, it is courted and made use of by the artists who make a trade of carving out excitement for their fellow-men.

'LOOKING BEFORE AND AFTER.'

This may be adopted as the general designation of a group of emotions having reference to things past, future, or distant, which can therefore be present only to the intellect. It is not, however, the mere fact of absence that gives a peculiar emotion to such things, for a beautiful scene excites the same feeling, whether we are looking at it or merely remembering it; the peculiarity arises from their influence on the present. In describing the higher activities, we shall have to allude to the effect of absent objects in stimulating Desire and Active exertion; at present we shall consider only one special case, which will be readily recognised under the denomination of 'Plot-Interest.'

The simplest form of this emotion is seen in the ordinary action of taking an aim, which is common to man with animals. The eye is fixed upon something within its reach, and the other organs are put in motion to secure it within their grasp also. The feeling that predominates between the moment of taking an aim and the complete possession of the object, is a distinct and often-recurring experience of human nature, and is what we here call plot-interest. It is remarkable for the intense way that it occupies the entire being, both body and mind, sense and activity. A nervous thrill passes through the whole of the system. An animal in pursuit of its prey, whether by chase or by climbing, and all the occupations of human beings that involve the taking of an aim

and the following up of a lead, exemplify the position that brings out plot-interest. Life is full of such cases, having all degrees of complication, from the simplest situation, as in applying food to the mouth, where the plot lies between the cup and the lip, up to the most complicated search that the intellect can be occupied with. Wherever an object is fully before the view, and the whole of the activity of the frame set in motion to approach it, and where a palpable progress is making, we have the circumstances calculated to bring out this emotion. Its intensity depends in the first place on the strength of feeling we have for the end in view, and in the next place, on the rapidity of the approach, and the nearness to the end. The engrossing power of the situation arises from its strongly inflaming some appetite, and through that the active organs of the frame; and the larger the amount of activity brought into play, the deeper the engrossment of the mind. In running a race, the interest is in proportion to the stakes, and is most intense as the goal is neared. An infusion of uncertainty, which communicates a slight tinge of terror to the emotion, increases the excitement of the contest.

The sports, pastimes, and pleasures most commonly resorted to for affording exhilarating and satisfying employment to human beings turn for the most part upon the emotion of plot. Field-sports, and games, and contests of strength and skill, are all of this character. Even in the stir of social assemblies, much of the action and reaction of man on man presents this kind of interest mixed up with other sources of satisfying excitement. In putting a question, and waiting for the answer, or in making a remark, and watching the response, there is a deliberate taking of an aim, and a moment of watching and suspense while looking for the effect.

In the literature of emotion, or the productions of literary art intended as a sort of higher pastime, plot-interest is a predominating feature.

Under the same head of 'looking before and after,' we must place the emotions of hope and fear, or the feelings that arise from the action of present circumstances on future plans, projects, expectations, and hopes. The human mind being capable of forming pictures and projects of the future, and being disposed to occupy itself as intensely with these as with anything present, it experiences a peculiar emotion when anything happens bearing on its remote interests. The intoxication of hope and expectation is often more powerful than any feeling of enjoyment of what is strictly present. Many men are peculiarly liable to be swayed by hopes and day-dreams, and the leaders of mankind have often acted on this weakness.

#### EMOTIONS OF SOCIABILITY.

The emotion of *Tenderness* is the most prominent of the feelings of Sociability, and is deeply rooted in the structure of the human frame. In its simplest form and manifestation it supposes two human beings, the one dependent upon the other for help, succour, or support; and it is contrasted with isolation, self-sufficiency, and independence. It produces a powerful sensation in the breast, extending to the organs of utterance and sight; and in its extreme state of violent outburst, it causes convulsions in the one and moist effusions in the other. The muscular response is further completed by the action of embracing in folded arms.

Nature has provided for this emotion such a large compass, and so many degrees of expression, that nothing less than some extraordinary occasion brings out its extreme manifestations, except in children, savages, and persons of great constitutional weakness of nerve. The feeling can be made apparent by a very slight tinge given to the tones of the voice, and by a certain well-recognised attitude of the eye, while the embrace is reduced to the simple shake of the hand; it being one of the refinements of civilized life to suppress all the violent exhibitions of passion, and employ only such as are mild, gentle, and suggestive.

This emotion shows to what an extent nature has formed human beings to depend on one another. It belongs to all men more or less, and in the average it bears a high proportion to the general capacity of emotion inherent in our nature. The institutions and arrangements of human life which flourish upon it are likewise numerous and engrossing.

Pity and compassion are very common forms of the feeling; but besides being limited to a single class of the cases coming under it, they express only the feeling on one side. The beings that are the objects of the compassion are themselves affected with the very same emotion (provided they respond at all to the feeling exercised towards them) as the persons who show the pity.

The affections at large are based on the tender emotion, and are expressed in part through its signs. Parental, filial, and fraternal love, and the feeling between dependents and superiors in general (when the relation is one of feeling, and not of worldly interest alone), and between men co-operating and sympathizing in some common object, are all supplied from this fountain. The attachment of the sexes involves it to a large extent, and the position assumed in the relation of man and wife is manifestly calculated to bring it constantly into play. Affection, in the ordinary sense, means a relation of habitual tenderness.

Pain, suffering, and violent shocks are apt to express themselves in an outburst of tender emotion; but this is to be regarded as a by-use, and not the main purpose of the feeling or of its instrumentality. Such a turn given to the expression of pain is like an appeal for help, or a confession of dependence. It may often be noticed that the outburst of grief is always accelerated by sympathy from a second party, owing to the natural effect in mutual feelings, for their expression in one person to bring out a corresponding expression in another. The most natural and primitive expression of pain in the isolated individual is the sudden retraction of the wounded part, followed up by the instinctive actions of rage, resentment, and hostility. It is always a sign of weakness, or of the strength of the emotion of dependence, when it passes into grief. The pains which most naturally and immediately cause grief are the pains of wounded affection.

Warm-heartedness, kindness, geniality, are common terms for the manifestations of tenderness, or for the characters where it is strong. Benevolence on the large scale is prompted by the same emotion, which may therefore be considered as one of the sources and main-springs of human goodness.

Veneration, reverence, or worship may be ranked next among the social emotions. The object of this class of feelings is dignity or greatness, which is another name for the possession of power of some kind or other. There is an attitude and an emotion caused by the aspect of power and might which is of a peculiar and distinct kind, tending to the prostration or bending of the body, whereas the carriage of greatness itself is extreme erectness of posture. The emotions of veneration and reverence are, as commonly understood, somewhat more complex than the mere bending to power: they generally imply something of love or of approbation and delight towards the character or nature of the power, being opposed to mere superstition or terror, where power causes quaking and dread. Some natures are so constituted as to be exceedingly sensitive to the aspect of dignity, majesty, and grandeur, and to delight in the posture of reverential homage; and as the world presents innumerable objects of this character, such an emotion will be frequently called into exercise. The principal practical effect of the susceptibility is to lead to a ready submission to the authorities and powers that rule over men.

Admiration is another feeling of the same class of sociable emotions. It couples together wonder and the feeling of power, and relates to what is not merely great, but surpassing in its kind, unexpected or inexplicable. It does not imply overpowering might so much as rare and surprising excellence, which delights us by setting

its ends, and astonishes us by our not being prepared by the ordinary course of things to meet with it. High virtues, great genius, and extraordinary energy and will, are among the objects of universal admiration.

Esteem is more of an intellectual effort than of an emotional outburst, and consists of a certain appreciation of the qualities and virtues of individuals in reference to their position, pretensions, and our tastes and standards of judging. The resulting emotion is expressed by such terms as respect, deference, and the accordance of position and regard. Such an emotion is the foundation of one of the forms of likings or attachments between individuals, or one of the bonds of sociability. All these emotions, of veneration, admiration, and esteem, have their opposites, whose definition is determined if the emotions themselves are clearly defined.

EMOTION OF THE LUDICROUS.

This emotion is exceedingly characteristic and distinct, both in the anatomy, the consciousness, and in the objects that bring it into action. The clash of the dignified, venerable, august, lofty, or great with what is mean, contemptible, poor, or insignificant, produces a conflict of attitude and emotion which is relieved by the outburst of laughter. The act of laughter is a series of convulsive expirations, which are as it were the descent from the tense, erect, dignified attitude of the body to the relaxed posture, or the posture that agrees with the absence of all feeling of power or worship, and with the presence of ease, carelessness, and abandonment. If an object that naturally possesses the aspect of dignity is accidentally brought into a position where it unavoidably assumes a character of vulgarity, degradation, or meanness, it is impossible to regard it in both lights at the same instant; for the human constitution cannot sympathise with two such opposite objects at one time; either we refuse to attend to more than one of the points presented; or we are torn on the rack of conflict; or nature takes its course, and we burst into laughter.

Humour is felt to be a higher, finer, and more genial thing than wit, or the mere ludicrous; but the exact definition of it has occasioned some difficulty. It is the combination of the laughable with an element of tenderness, sympathy, warm-heartedness, or affection. Wit, sweetened by a kind, loving expression, becomes humour. Men who have little tenderness in their nature, or whose language and manner are destitute of soft, warm, and affectionate feeling, cannot be humorists, however witty they may be. There is no humour in Butler, Pope, Swift, Dryden, Ben Jonson, or Voltaire.

EMOTION OF SIMILARITY.

The intellectual power of like recalling like, even out of remote positions and distinct circumstances, produces a distinct agitation or thrill of feeling that deserves to be reckoned as a separate emotion. All the discoveries of identification, where use and wont is suddenly broken through, and a common feature made known among objects previously looked on as entirely different, produce a flash of agreeable surprise, and the kind of peculiar sparkling cheerfulness that arises from the sudden lightening of a burden. The variety and complexity of the world acts like a weight or pressure on the human intellect, and every case of newly-found identity is a diminution of the weight: the labour of comprehension being reduced by the discovery. To understand the fall of bodies on the earth and the motions of the planets, required two separate efforts of study before the time of Newton; but now one study serves for both. The first effect or flash on the mind of such identities in the midst of endless variety is always startling and agreeable. The same effect happens from happy comparisons or illustrations, which save the labour of the intellect in comprehending some difficult matter, by recalling something exactly similar from among our previously-understood and familiar conceptions, as when a bellows is brought to mind in order to make known the struc-

ture of the lungs. The identification of common features in the characters of men and societies in distant regions and remote ages, has the same cheerful, enlivening effect. It is like the encouraging stimulus that we derive from a stroke of success, or a sudden lightening of our load of labour and care. It is one of the prerogatives of human genius to furnish such identifications and comparisons, and in this way to ease and enchant the course of human existence.

FITNESS—KEEPING—HARMONY—BEAUTY.

These emotions all result from certain intellectual relations of sensible objects, and they are closely allied with the emotion of similarity. They all suppose, more or less, some coincidence, likeness, or common effect, among things which at first sight seem unconnected and irregularly varied; and their influence on the mind is of the lightening, cheering, and encouraging kind—'a thing of beauty is a joy for ever.'

When any work has to be done, any difficulty or resistance to be overcome, the party having the thing in hand naturally feels a certain sense of pressure or weight in contemplating or conceiving it. The actual accomplishment of the task is the natural and obvious relief to the pressure. But it is also lightened by the perception of any set of means that seem peculiarly fitted for the end in view. Any tool that achieves its object easily, and with all the appearance of ease, is an object of agreeable emotion. A sharp, clean knife, a well-fitted, smooth-going set of machinery, and everything that not only does its work well, but does it in a way to suggest that it does it easily, give manifest pleasure to the beholder. A powerful, healthy animal frame is a pleasurable object, from its suggesting power and facility in accomplishing its work. One of the beauties of dress arises from its appearing to give great ease and freedom to the animal movements.

All complex objects and scenes which strike the mind through several avenues at the same time, have the chance of producing currents of thought and feeling that either agree or disagree with one another. The agreement causes a pleasurable emotion, the disagreement the reverse. If we see a rich man refusing himself the comforts of life, we suffer from a conflicting impression, and we describe the fact as being out of keeping, inconsistent, and discordant. On the other hand, a person who acts in all points, and puts on all the appearances consistent with his position, character, and duties, is an object of agreeable emotion. We often say that houses ought to be in keeping with their inmates, and with the purposes they are to serve; and we have a distinct pleasure in finding that they are so. It is not difficult to understand that all conflicting trains of association, thought, and feeling, must be painful, weakening, and paralyzing to the human constitution; while the concurrence of the same trains from different quarters gives a feeling of lightness, strength, and support. The standing object of man must always be to overcome the resistance to his path, to reconcile opposition, and bear burdens; and everything that reduces the amount of the burdens, or increases the sources of support, will be a direct source of happiness or of pleasurable emotion; and all the appearances about us that solicit our attention will be lightening or oppressive according as they communicate a concordant or a discordant set of impulses.

There is an effect produced in the various fine arts, which is in fact the very essence and cream of art itself, or the most genuine artistic impression. It is what is called harmony and melody in music; picturesque in painting; keeping in poetry; and fitness and suitableness of the parts, exquisite adaptation, and the essence of beauty, in all the regions of art. When we put a number of like things together, as soldiers in a line, there is an agreeable feeling of order and uniformity; but the force of art lies in joining two or more things of different composition and make, which nevertheless produce a fine harmonious feeling. It is in Greek architecture, the harmony of the columns

and the entablature; in Gothic, the harmony of the spire with the arch; and in all styles, the harmony of the decorations with one another and with the main body. In sculpture, it is the suiting of expression to mind, and of attitude and drapery to expression. In painting, it is the composing and grouping of things such as will in different ways excite the same emotion. In speech, it is the suiting of the action to the word, the sound to the sense. In poetry, which combines the spirit and effect of music and painting, the scope for fine harmonies is unbounded.

ACTIVITIES.

Under the heads of Reflex Acts, Appetites, and Instincts, we have already noticed a certain number of the capacities for action belonging to the human constitution. Under the present head we are to consider a higher order of active powers; namely, such as are regulated by intellect or connected with the emotions.

DESIRES.

These are analogous in their nature to the appetites. They express the cravings or longings of an unsatisfied system for some objects that are imagined or conceived capable of satisfying it. They originate in an irritation of some part of the frame, which suggests to the intellect certain objects that would allay it; and the bent of the mind becomes in consequence occupied upon these objects, to the exclusion to a certain extent of other trains of thought and emotion. The Appetites are confined to the Sensational circle, but the Desires extend to the circle of emotion and intellect, and take in all the gratifications that are associated with the higher regions of mind. Among the most conspicuous and pressing of the ordinary Desires of mankind, we may cite the following:—

*Avarice*, or the desire of wealth, or of the aggregate of material advantages resulting from human labour, and exchangeable in the commerce of the world. The longing for food is an appetite; the longing for money, which will procure food at any time, as well as other things, is an intellectualised longing or a desire; the associations of intellect are interposed between the thing actually enjoyed and the thing longed for. Habit often has the effect of making the desire terminate in the money, and cease to have any regard to the primary objects of enjoyment with which it was originally associated.

*Ambition*, or the desire of power, grandeur, influence, importance, admiration, and worship among our fellow-men. As human nature is formed to be intensely gratified by power and influence on the one hand, and by admiration, homage, and esteem on the other; and as it is easy to conceive to one's self, or to imagine the possession of these attributes, they readily become objects of ambition. The more obvious and conceivable gratifications are always indeed the most popular, and the most eagerly sought after.

*Curiosity*, or the love of knowledge, is a more intellectual kind of desire than either of the others. It supposes a mind alive to the emotions attending the acquisition and possession of knowledge, and of those identifications that increase the sphere of human insight into the world. In this, as in all other desires and appetites, the enjoyment of a certain amount of gratification suggests a still larger amount to the imagination, and thereby creates the desire.

The desire of *self-cultivation* and of the high development of one's own nature and faculties, is one of the most elevated of our desires, proceeding on a strong appreciation and estimate of the higher qualities of human nature. There must be in the mind so actuated a susceptibility to human worth, either from a perception of what is best in one's self, or from a discrimination of the finest qualities of others. There can be no desire unless an idea is formed of the object, and unless this idea is capable of exciting some lively emotions, which emotions are the mainspring of the desire.

Desire is to be contrasted with satisfaction, contentment, satiety, and serene enjoyment of the present. Contentment is the happiest condition of man. Desire has always in it something of the nature of an internal conflict or opposition of states, and it is therefore so far a source of waste, disquietude, or unhappiness; but it is one of the preliminaries of energetic activity and determination directed to the accomplishment of great objects. Nevertheless, for the peace and harmony of the individual, it is essential that Desire should always as soon as possible be swallowed up, either in contentment or in action, both which states are consistent with the most perfect union of all the powers of the system.

HABITS.

As the Desires are parallel to the Appetites, so the Habits correspond to the Instincts: they refer not to the stimulants to action, but to the capacities and means of acting.

We have already shown that the instincts become perfect under the operation of the law of sensational growth, and that on this consideration walking is to be considered as an instinct and not a habit. The true habits are best marked out in the class of cases where actions are acquired that are opposed to the instinctive tendencies, as in some mechanical processes where the rythmical action of the two arms is contradicted. For example, in hammering a piece of iron, the motion of the arm that welds the hammer is totally different from the motion requisite to hold the hammered rod. Such an exertion can only be learned by subduing an instinct. The confirmation of an instinct takes place through the law of sensational growth; the contradiction of an instinct and the formation of a habit depend on the force of intellectual growth expressed by the law of contiguity. The manner of originating habits is well known. We must by some effort of will, imitation, or external compulsion, place the organ in a certain position, or force it to go through a series of movements a great number of times; and in the course of this repetition or prolonged action, a cohesion grows up between the different steps of the process, and at last they succeed one another independently of the compulsory effort that first joined them together.

We have therefore in each case of habit, 1st, Some power capable of communicating a bent or a series of movements to some of the organs of the body or mind; 2d, The continuance or repetition of the process; 3d, The operation of the adhesive power named the force of contiguity, either to contradict an instinctive series of movements or originate some separate and distinct series; 4th, The resulting confirmation of the bent or train desired to be imparted to the system.

The mechanical arts and the bodily carriage require a training, or a class of habits to be communicated to the general bodily mechanism. The soldier has to learn a peculiar set, and peculiar trains of movements, in decided opposition to the bent of the untutored rustic, who has allowed his instinctive movements to have free scope, and who comes into the army with all the characteristics of the natural man.

The repression of instinctive movements is implied in habits of self-command, coolness, and composure under irritation or some exciting stimulus. This repression is at first effected by strength of will, by imitation, or by external compulsion, and in the end becomes habitual and easy. The resistance to terror, which is a powerful emotion springing from a natural instinct, may likewise be formed into a habit of courage. Habits of obedience are created in opposition to self-will, and to the instinctive tendency to follow out one's prevailing temper. Habits of authority have to be acquired in spite of the disposition to sympathise with our fellow-beings under all circumstances. Habits of promptitude, activity, and alertness are frequently the result of a long-continued contradiction of the natural character. Habits of grace and polite demeanour are in many persons a growth forced entirely from without, and not coinciding with a single tendency of the na-

tural man. The native instincts and emotions may be overpowered by habits, or in persons where any of them are deficient, they may often be replaced by habits.

When a natural susceptibility is increased by exercise, as in the perfecting of the senses, we prefer to call this a case of sensational rather than intellectual growth; but the communication and improvement of the higher tastes and sensibilities, such as the sense of beauty, is a case of purely intellectual growth, and is therefore properly considered as a habit.

The capacities of human nature in general are a mixture of primitive impulses and instincts with acquired habits. Some natures come into the world far more richly endowed with instincts than others; and some have the advantage of an aptitude for fixing habits, and of opportunities of forming them. The strength of the adhesive force of contiguity is the measure of the rapidity of converting attempts and instruction into habits. But as all such acquisitions are identified with the processes of the organic growth of the system, they are most easy in early life, when this growth is most rapid, and they are weak in old age and in times of declining health. When new habits have to be formed, the best circumstances for their growth are such as are favourable to the freshness and vigour of the nervous and muscular systems. The processes of mind depending on the intellectual power that we call similarity, are not so dependent on the vitality and growing vigour of the frame as the processes coming under contiguity.

BELIEFS.

The nature of belief or faith has had occasion to be intensely and widely discussed, as being involved in some of the fundamental doctrines of the Christian faith.

The thing to be chiefly kept in view in settling the nature of faith is, that it is a thing not of the intellect solely, but also and mainly an active principle, impulse, or force, operating upon human nature to cause it to act or to resist action. Our desires, passions, and impulses, are often suppressed by the power of our beliefs. It is by faith that a burnt child avoids the fire.

Belief must always have a reference to action; without this it has no meaning. When we go to work with the view of producing some effect, it is on the ground that a certain action of ours will be followed up by some other things that we desire to happen. We go to rest at night, believing that we shall awaken in the morning refreshed; we labour, in the belief that we shall be rewarded; we lay up store for the future, in the faith of its being preserved to us by the laws of our country. Belief implies knowledge, or the possession of some facts, truths, or propositions about the world; and it implies further, that these have been so engrained in our minds, or that the sequences and conjunctions implied in them are so firmly associated together that they form a link in our actions, and that we feel sure of the eternal constancy of the tie that binds them together. When we throw water on a fire to quench it, we do so by the force of our determination to quench the fire, joined with our belief in the fact that water will have the desired effect; and the more firmly the two ideas of the application of water and the extinction of fire are rivetted in our head, or the stronger our faith in the sequence, the more unhesitatingly do we proceed to act upon it. But in cases where the tie is weak, the action is vacillating and undecided. Belief of some degree or other is co-extensive with knowledge, or with propositions or affirmations respecting the order of nature and the course of events.

Some of our beliefs are instinctive, and anticipate our experience of nature. Every instinct that leads us to perform an action for the sake of a subsequent effect involves a belief. But the most important of our instinctive beliefs, is the belief that we have in the uniformity of nature, and in the resemblance of the universe at large to the parts that we have had experience of. We cannot think of the distant and unseen without supposing it to be analogous to something that is

present or seen, and we act upon this assumption. We cannot help believing that other human beings are like ourselves, and that we will always continue in our present way of thinking and feeling: nothing but a laborious intellectual process, and much labour and experience, will dispossess us of these primitive convictions of our being. When they are once modified and corrected they are of great value to us, but in their original shape they are very far from the truth.

All our active tendencies involve beliefs or convictions, and the action often suggests the belief. He that has a strong desire for stimulants, generally has the belief that they are for his good: and our partialities for individuals make us believe in their being possessed of good qualities without any other evidence. Making, as we always do, the sweeping assumption that our own actions and conduct are exactly what they ought to be, we are led into many minor assumptions and beliefs as necessary consequences.

There is a certain class of assertions that sometimes receive the name of moral truths, because they affirm moral qualities and obligations: as when we say justice is right; the laws of the country are obligatory upon its citizens; to show mercy is a virtue. Such persons as are strongly penetrated with these maxims, and disposed to act upon them on all occasions, may be said to have strong faith in them; and they that make light of them, or set them aside from trivial motives, are said not to believe them. In the same way there are religious truths—such as, 'God is good'—and the intense possession of them, with a practice corresponding, is called religious faith. It must, however, be admitted, in reference both to the moral and the religious impressions, that 'faith,' or 'belief,' is a somewhat awkward mode of expressing them.

The faith that above all others dignifies and perfects human nature, is faith in evidence or in proof; which means, in other words, a belief in what is found in nature on a careful and sufficient examination. There are certain tests or criteria of whether or not a statement agrees with the fact of things, and these tests are called the proof or evidence of the affirmation; and when a man has brought himself to appreciate these, and to bow to them with the whole force of his nature, he may be considered to be a truly rational being, or a being at one with the decrees and ordination of the world. This faith in evidence is not an instinct, but a growth confirmed by the force of habit, and acquired in defiance of many of our most powerful natural impulses. It is produced by large dealings with the actual world, and by the cultivation of the exact sciences, or the departments of knowledge which have been brought to express with perfect accuracy the inviolable order of nature.

IMITATION—SYMPATHY.

We had occasion to speak of a certain class of emotions as the emotions of sociability; and we have likewise a class of activities that might be entitled sociable activities. They are the forces given forth by one human being, and influencing other human beings, and their tendency is to produce a harmonious or common action in aggregates of men. In this way society is formed, and brought to act like an individual. We have seen that there is an instinctive law of human nature for the purpose of harmonising the attitudes and actions of the various organs of the human system; we have now to recognise the more extended impulse that causes man to act upon man till a harmony arises through each collective mass of human beings.

Imitation and Sympathy are names used for one and the same peculiarity, which we may describe by saying that the expression and outward actions of one man have a tendency to stimulate a corresponding state of mind in all other men that have occasion to witness them. In the great majority of cases, the full effect is prevented by the action of some of the other forces of human nature; but the influence still exists. It extends to every feeling and state of mind that can

be embodied in a distinct outward expression. We find it to be a common remark, that the strong outbursts of emotion are infectious; people can rarely stand unmoved before the influence of laughter or tears. Enthusiasm of any kind, which means an intense exhibition of some particular emotion, is always catching. The strong expression of reverence or admiration is apt to find its echo in all bystanders. The gait and manner of one man may be communicated to the persons about him if they are of the susceptible character. The unoccupied minds and undecided activities of the young are shaped by spontaneous and unconscious imitation to a still greater extent than by express rules or formal guidance. More widely still, imitation impresses a common cast upon the language and manners of families, tribes, and nations, and perpetuates the same forms from generation to generation.

The imitation may be of very obvious and conspicuous bodily actions, or it may reach to the subtlest peculiarities of mind. In the one case it is a mere instinct, in the other it is an instinct extended by intellectual associations. The literal copying of an outward act needs no intellect, as we may see in the case of repeating a sound or a gesture; but when we imitate the modes of thinking of other men, or embody in our own language the thoughts that reach us in the language of others, there is an express effort of the powers of intellect requisite; more especially the powers of similarity and constructive association. The instinctive imitation or literal copying is within the capacity of many animals; and some races of men, such as the Sclavonic populations, possess the power in high perfection; but the imitation of an idea, so as to put it into different forms and language, is an act that shows a considerable force of intellect. Sir Christopher Wren's imitation of St Peter's is very different from the practice of literally copying Greek temples in every imaginable kind of building.

It has been common to designate certain of the fine arts, such as sculpture, painting, and poetry, Imitative Arts, and to ascribe their origin to the innate tendency of man to imitation, thereby recognising the production of likenesses or similitudes as one of the active principles of human nature.

THE WILL.

This is reckoned the highest and noblest of all the active impulses of man. Its operations are based on intelligence, and they are intended to enforce the conclusions of the reason against the instinctive and passionate impulses. By the intellect we make large generalisations of what is good for the future as well as for the present, and of what is good for society at large as well as for the individual; and in obeying the rules dictated by these intellectual considerations we are often unsupported by any instinct, habit, or imitative impulse; and were there not a large reserve of power in human nature we might rarely be induced to act in such cases at all. But in the very seat of intelligence itself there is a central force that gives impetus to its suggestions, exactly as the ganglia of sense and instinct send forth the requisite stimulus to the active organs of these circles. The power of the appetites and passions diminishes according as the object is distant and faintly perceived; the mere prospective knowledge that we will be hungry a year hence would not produce the same vigorous action as a present hunger, and would not produce action at all but for there being an additional centre of power attached to the region of intellectual associations. Obedience to remote and general views, and to what can only be conceived by the intellect, proceeds from this centre, to which we commonly give the name of Will. When we conceive to ourselves some extensive scheme that shall involve our whole life, and that we are urged to, not by some single appetite or instinct, but by an intellectual appreciation of our whole character and being and the circumstances that surround us, and conclude upon a line of action for carrying the scheme

into operation, the execution will mainly depend upon our will, or on the force that usually goes along with the decisions of the intellect. No doubt the scheme being adapted to the collective impulses of our nature ought to be supported by these, but as it cannot agree with every impulse at every time, and as in some aspects it may be wholly repugnant to us, it would come to a stand if there were not a force independent of sense, appetite, instinct, emotions, desires, habits, and imitation, to carry us over the intervals when these are dormant or are opposed to our plans. Were it not for the power imbedded in the centre of intelligence, forethought would be quenched every day of our life by some strong impulse of our inferior nature. The desire of ease at one time and of excitement at another, the gratification of appetite, and the predominance of strong emotion, would be more than sufficient to counterbalance duty or prudence, if there were not a peculiar and distinct tendency or power to carry into effect the results of reason or the judgments grounded on our intelligence.

The character of Will in an individual will depend very much on the character of the intellect, or on the kind of considerations that it can most readily entertain. It is impossible that action can be more elevated than intelligence, or that a man can carry into effect more than he sees. The strength of Will does not increase with the strength of the intellect, but the one will always act along with the other. Energy following up reason and the generalities of prudence, right, and social good, and tested by overcoming occasionally all the inferior propensities of one's being, is the true definition of will; and the more elevated the character of the intellectual grasp, the more does the will stand apart from the other forces and activities of the being. When a man forms very refined and lofty ideas of prudence, self-culture, or social and moral duty, such as will require the restraint or suppression of many powerful impulses and instincts, and when his resolution is powerful enough to carry these into full effect, he must be reckoned a man of singularly powerful will as well as of elevated susceptibilities and intelligence. There is in some men a general temperament of activity or a strong tendency to action in every way that may be open to them, extending over all the specific impulses of the frame. In such men the force of pure will does not stand out so clearly as in the class whose temperament is naturally passive and susceptible, but who, on the spur of intellectual determinations, exert an unremitting energy of executive force.

The actions where a strong will is most required are such as, while they are at variance with many powerful propensities, are also opposed to common usage, or use and wont in the world at large, and of a kind that the individual is unaccustomed to. With opposing instincts, opposing habits, and, at the same time, an opposing social exterior of public opinion, any kind of proceeding must be intensely difficult, and must require a high development of pure will.

Excitement is apt to come into comparison with Will, and to be confounded with it. There is such a thing as a temporary increase of the whole activity or energy of the system, which enables a man for the time to excel himself, a reaction of languor and weakness being apt to succeed to it. But the proof of a strong will as against mere excitement is an unremitting and continued course of action, which may call for strong effort at any moment, and which is incompatible with intervals of weakness and irresolution.

Having now given a slight sketch of the chief elementary powers and peculiarities of the human mind, we ought next to go on to the consideration of the complex faculties and susceptibilities, such as OBSERVATION, MEMORY, ABSTRACTION, REASON, JUDGMENT, IMAGINATION, CONSCIENCE, GENIUS, &c.: but the discussion of these is not possible within our narrow limits, and we must therefore refer the reader to such works as those of Locke, Bacon, Reid, Stewart, and Brown.

## PHRENOLOGY.

PHRENOLOGY is a Greek compound, signifying a discourse on the mind. The system which exclusively passes by this name was founded by Dr Francis Joseph Gall, a German physician, born in 1757. Dr Gall was led, when a schoolboy, to surmise a connection of particular mental faculties with particular parts of the brain, in consequence of observing a marked prominence in the eyes of a companion who always over-matched him in committing words to memory. Finding the same conformation in others noted for the same talent, he reflected that it was possible that other talents might be accompanied by external marks, and that dispositions might also be so indicated. He devoted himself to observing marked features of character; and on examining the heads, was struck with differences in their forms, there being prominences and hollows in some not found in others, with corresponding variations of character in the individuals. After most extensive and accurate observation, he first lectured on the subject in Vienna in 1796. There his lectures were suppressed by a jealous and ignorant despotism; upon which he abandoned Germany and settled in Paris, where he practised as a physician, and studied and extended his 'doctrine,' as he always called it, till his death in 1828. His great work, with its illustrative engravings, is one of the most extensive and beautiful examples of inductive evidence of which any science can boast. Dr Gall never took any particular step for making phrenology known in our island. With some slight exceptions, the science was not heard of in Britain till introduced by Dr Spurzheim in 1815. He was a native of Treves on the Moselle, born in 1776, the pupil, and, from 1804, the associate of Gall. Besides making many valuable discoveries in the anatomy and physiology of the brain, and ascertaining several organs in addition to those discovered by Gall, Dr Spurzheim had the distinction of systematising the discoveries of both into a harmonious and beautiful mental and moral philosophy. He died at Boston in the United States in 1832. Since then, the recognised head of the phrenological school has been Mr George Combe of Edinburgh, author of many popular works on the science, and its most successful teacher, by his public prelections in Britain and America. The applications of phrenology to insanity, health, and infant education, have been at the same time admirably made by the late Dr Andrew Combe. Whatever may be thought of phrenology as a system of mental philosophy, it is undeniable that its adherents have taken a lead in many social improvements, and shown the practical utility of their doctrines.

### PRINCIPLES OF PHRENOLOGY.

The brain is the organ by and through which mind is manifested. Formerly, it was believed that *mind* and *body* were two distinct entities, and they were accordingly treated of separately by two orders of philosophers—the metaphysicians and the anatomists. In vain the metaphysician was it obvious that we have no knowledge of mind but through the medium of a bodily apparatus, with which it grows and decays; he continued to treat of mind as a spirit unconnected with body. The anatomical investigator reasoned quite as unphilosophically when he assumed that mind was nothing but matter, the higher qualities of which were to think and feel. The phrenologist says he avoids both these assumptions. He does not pretend to know, much less to assume, the *essence* or nature of either mind or matter. Whether they are one or distinct is known only to the God who made them; and whatever they are, they must therefore be the best possibly adapted to their end and design. The phreno-

logist disclaims materialism, but affirms that mind can operate only by means of some kind of corporeal organisation. To all sane manifestations of mind, he maintains that brain in a healthy condition is necessary. In sleep, fainting, and compression of the brain, mind is suspended. Were it an immaterial spirit, acting independently of the brain, the repose of the material brain could not suspend the spirit's working. Pressure on the brain instantly suspends consciousness. Mr Combe, in his 'System of Phrenology' (4th edition, p. 14), describes several most interesting and instructive experiments on compression, as made by Richerand, Cooper, Chapman, Cline, and others. Pinel clearly traces to a *bodily* cause the diseased manifestation of mind called insanity, by the following case:—'A man engaged in a mechanical employment, and afterwards confined in the Bicêtre, experiences at irregular intervals fits of madness characterised by the following symptoms:—At first there is a sensation of heat in the abdominal viscera, with intense thirst and a strong constipation; the heat gradually extends to the breast, neck, and face, producing a flush of the complexion; on reaching the temples it is still greater, and is accompanied by very strong and frequent pulsations in the temporal arteries, which seem as if about to burst; finally, the nervous affection arrives at the brain.' What, then, follows? All the effects hitherto described are purely corporeal. Pinel proceeds—'The patient is then seized with an irresistible propensity to shed blood; and if there be a sharp instrument within reach, he is apt to sacrifice to his fury the first person who presents himself.' How powerfully this case connects mind and brain, and what a strong light it sheds upon that really bodily, that is, cerebral disease called insanity! The brain, when exposed, has been seen *in action* during emotion, conversation, dreams, &c. Sir Astley Cooper refers to the case of a young man who had lost a portion of skull above the eyebrow. 'I distinctly saw the pulsation of the brain,' says Sir Astley; 'it was regular and slow; but at this time he was agitated by some opposition to his wishes, and directly the blood was sent with increased force to the brain, and the pulsations became frequent and violent.' Blumenbach observed a portion of exposed brain to sink during sleep, and swell when the patient awoke.

From the above facts phrenologists assume:—*1st*, As there is no vision or hearing without their respective organs, the eye and ear, so there is no thinking or feeling without their respective organs in the brain; *2d*, Every mental affection must correspond with a certain state of the organ, and *vice versa*; *3d*, The perfection of the mind will have relation to the perfection of its organs. According to this doctrine, therefore, the study of the cerebral organs is the study of the mind, in the only condition in which we can cognize it.

The brain being the general organ of the mind, we come next to inquire whether it is *all* necessary to every act of feeling or thinking; or whether it is divided into parts, each part being the instrument or organ of a particular mental act. *1st*, It is a law of organisation that different functions are never performed by the same organ. The stomach, liver, heart, eyes, ears, have each a separate duty. Different nerves are necessary to motion, feeling, and resistance, and there is no example of confusion amongst them. Analogy, therefore, is in favour of the conclusion that there are distinct organs for observing, reflecting, and feeling kindness, resentment, self-love, &c. *2d*, The mental powers do not all come at once, as they would were the brain one indivisible organ. They appear successively, and the brain undergoes a corresponding change. *3d*, Genius varies in different individuals: one has a *turn*, as it is

called, for one thing, and another for something different. 4th, Dreaming is explained by the doctrine of distinct organs which can act or rest alone. Its disjointed images and feelings could never occur if the brain acted as a whole. Undivided, it must either all sleep or all wake; so that there could be no such thing as dreaming. 5th, Partial insanity, or madness on one point, with sanity on every other, proves the distinction of organs, and their separate action. 6th, Partial injuries of the brain, affecting the mental manifestations of the injured parts, but leaving the other faculties sound, prove distinctiveness of organs. 7th, There could be no such state of mind as the familiar one where our feelings contend, and antagonise and balance each other, if the brain were one organ.

These are grounds for presuming that the brain is not single, but a cluster of organs, or at least that it is capable of acting in parts, as well as in whole. For this conclusion the phrenologists have found satisfactory proofs in repeated observations, showing that particular manifestations of mind are proportioned, in intensity and frequency of recurrence, to the size or expansion of particular parts of the brain, and are thus to be presumed to depend on those parts. This is a law everywhere seen affecting organic nature; a large muscle, the conditions of health, quality, and outward circumstances being the same, has more power than a small one. The same is true of a nerve. Dogs have very large nerves for smelling, eagles for seeing, &c. A child's brain is smaller, and its mental power weaker, than those of an adult. A very small brain in an adult is the invariable cause of idiocy. A large head may be idiotic from cerebral disease, but a very small head, from defect of size alone, is always idiotic. Men of great force of character, such as Napoleon, Franklin, Burns, &c. had brains of unusually large size. Powerful energetic nations exceed weaker ones in size of head, and invariably, when brought into collision with them, overcome them. The average European head is to the average Hindoo as the head of a man to that of a boy; hence the conquest and subjection of a hundred millions of the latter by thirty thousand of the former. The general law, then, being that size of organ is accompanied by power of manifestation, we proceed to inquire, secondly, if there are any circumstances, and what these are, which modify this law. It will be found that quality of brain is a modifying circumstance, also health of brain, and exercise of brain.

Phrenologists conjectured that different brains differ in quality, but were long without any indications of these differences. The doctrine of the *Temperaments* has thrown considerable, though not perfect light on this point, and for this we are indebted to Dr Thomas of Paris. There are four recognised temperaments, accompanied with different degrees of power and activity—in other words, quality—of brain. These are the *bilious*, the *nervous*, the *sanguine*, and the *lymphatic*. The predominance of these several bodily systems is indicated by certain sufficiently obvious external signs, whence our power of recognising them, as fully described under ANIMAL PHYSIOLOGY, Vol. I. p. 125.

The brain must be in a healthy condition to manifest itself properly in the mental faculties. The phrenologist must therefore inquire into this circumstance, as the external development does not reveal it.

Exercise—or whether or not, and how, the brain has been exercised—is another condition to be inquired into before judging of two individuals similarly organised. The brain which has been the more and more judiciously exercised, will, other things being equal, manifest the greater degree of activity and power.

If size of organ implies vigour of function, it is of great moment in what region of the brain the organs are largest—whether in the animal, moral, or intellectual. On this preponderance depends the character. Two brains may be exactly alike in size generally, yet the characters may be perfect contrasts to each other. For example, there is nearly as much brain in fig. 2 as in fig. 1; yet fig. 1 is the head of Melancthon, the

most virtuous and talented of the reformers; while fig. 2 is the atrocious criminal Hare, who murdered by wholesale for gain. The superiority of fig. 1 in intellect is obvious by one glance at the high and full forehead,

Fig. 1.

Fig. 2.

compared with 'the forehead villainous low,' as Shakespeare would have called it, of fig. 2. The horizontal line in fig. 2 shows the shallowness of moral brain. A line drawn from the same points in fig. 1 would show a much greater depth; while the mass of brain behind the ear in fig. 2, compared with fig. 1, shows the preponderance of animal brain in the former.

PRIMITIVE FACULTIES OF MIND, AS CONNECTED WITH THEIR ORGANS IN THE BRAIN.

Mind, which was considered by the metaphysicians as a single thing or essence, was said by them to be capable of being in different states, in each of which states it made one of its various manifestations—as memory, judgment, anger, &c. In no particular does the phrenological hypothesis differ more from the metaphysical than in this. The phrenological doctrine is, that the brain, the organ of the mind, is divided into various faculties, each of which has its own modes of acting. It is accordingly held—

First, That by accurate observation of human actions, it is possible to discriminate the dispositions and intellectual powers of man—such as love, anger, benevolence, observation, reflection, and so forth.

Secondly, That the true form of the brain can be ascertained from the external form of the head; the brain, though the softer substance, being what determines the shape of the skull.

Thirdly, The organs or parts into which the brain is divided, all of which organs are possessed by every individual except in the case of idiocy, appear on the brain's surface in folds or convolutions, somewhat like the bowels or viscera of an animal, but have a well-ascertained fibrous connection through the whole substance of the brain with one point at its base, called the *medulla oblongata*, which unites the brain to the spinal cord. The organs have thus each a conical form from the medulla oblongata to the surface.

Fourthly, The brain is divided into two equal parts called *hemispheres*; on each side of the fosse or division between these hemispheres the same organ occurs; all the organs are therefore double, in analogy with the eyes, ears, &c. But when the term *organ* is used, both organs are meant. The organs which are situated close to the middle line vertically drawn on the head, though close to each other, are nevertheless double; for example, Individuality, Benevolence, Firmness, &c.

Fifthly, Besides the brain proper, there is a smaller brain, lying below the hinder part of the base of the main brain, called the *cerebellum*.

Sixthly, The brain, including the cerebellum, is divided into the *anterior*, *middle*, and *posterior lobes*. The cerebellum forms part of the posterior lobe. The anterior lobe contains all the intellectual faculties; the posterior and lower range of the middle lobe are the regions of the animal propensities; while the moral sentiments are found to have their organs developed on the top or coronal region of the head.

# PHRENOLOGY.

The gradation in size of the organs is denoted by the generality of phrenologists as follows:—

Very Small. Small. Rather Small.	Moderate. Rather Full. Full.	Rather Large. Large. Very Large.
--	------------------------------------	--

In practice, the general size of the head is measured in several directions with calliper compasses. Twenty males, from 25 to 50 years of age, measured, from the occipital spine (the bony knot over the hollow of the neck) to the point over the nose between the eyebrows, on an average,  $7\frac{1}{2}$  inches; some of them being as high as 8 2-8ths, and others as low as  $6\frac{1}{2}$ . From the occipital spine to the hollow of the ear, the average was  $4\frac{1}{2}$ ; some being as high as 5, others as low as  $3\frac{1}{2}$ . From the hollow of the ear to the point between the eyebrows, as above, average nearly 5; some being  $5\frac{1}{2}$ , others  $4\frac{1}{2}$ . From the same hollow of the ear to the top of the head, about an inch behind the centre (the organ of Firmness), the average was 5 9-10ths; some being  $6\frac{1}{2}$ , others  $5\frac{1}{2}$ . Across the head, from a little below the tops of the ears (from Destructiveness to Destructiveness), the average was 5 8-10ths; some being  $6\frac{1}{2}$ , others  $5\frac{1}{2}$ . The averages are in these twenty individuals higher than those of the natives of Britain generally, some of them being large, and none small.

It ought never to be lost sight of that, in estimating character from development, it is not legitimate to go out of the same head, and compare any organ with the same organ in another head. This will never ascertain the effect of a particular organ in the head where it exists; and for the plainest reason, that character is another word for the most powerful organs, as modified by their neighbours in the same head. A virtuous person may have the organ of Destructiveness absolutely larger than a person remarkable for a violent disposition; but it will be found that there are moral faculties to control, or that there has been education to modify, in the one person, and not in the other. In studying phrenology, however, different heads may be compared, in order to observe where particular organs are absolutely large, and where they are absolutely small.

We have said, the larger the brain, and of course the head, the more the power. The old adage, 'Big head, little wit,' is often true, but not always. It is true when, with a large brain, there is a lymphatic temperament, or when some damaging or deranging circumstance has taken place, to deprive the brain of its natural power, or when the largeness is not in the intellectual region. It is to be remarked, however, that even large animal brains have great animal power, in spite of their intellectual deficiency. A moderate-sized head, of which the brain is chiefly in the anterior or intellectual region, will have much more wit or cleverness than the other. Its power will be intellectual.

Phrenologists further distinguish between *power* and *activity* in the mental faculties. Power, in whatever degree possessed, is *capability* of feeling, perceiving, or thinking; while activity is the *exercise* of power, or the putting into action the organ with more or less intensity. An individual, for example, may possess great power of destruction, and yet it may remain quiet, and the individual be perfectly calm. His large Destructiveness, however, will be more prone to start into activity than a smaller would. Activity is measured by the rapidity with which the faculties act.

The powers of mind, as manifested by the organs, are called *faculties*. A faculty may be defined to be a particular power of thinking or feeling. A faculty has seven characteristics, in order to our concluding it primitive and distinct in the mind—namely, 1. When it exists in one kind of animal, and not in another; 2. When it varies in the two sexes of the same species; 3. When it is not in proportion to the other faculties of the same individual; 4. When it appears earlier or later in life than the other faculties; 5. When it may act or repose singly; 6. When it is propagated from parent to child; and 7. When it may singly preserve health, or singly manifest disease.

## DIVISION OR CLASSIFICATION OF THE FACULTIES.

The faculties have been divided by Gall and Spurzheim into two great orders—FEELING and INTELLECT, or AFFECTIVE and INTELLECTUAL FACULTIES. The Feelings are divided into two genera—the *Propensities* and the *Sentiments*. By a propensity is meant an internal impulse, which incites to a certain action, and no more; by a sentiment, a feeling which, although it has inclination, has also an emotion superadded.

The second order of faculties, the Intellectual, also suffers division into the *Perceptive* or *Knowing*, and the *Reflective Faculties*. The Perceptive Faculties are again divided into three genera—1st, The *External Senses* and *Voluntary Motion*; 2d, The *Internal Powers* which perceive *existence*, or make man and animals acquainted with external objects and their physical qualities; and 3d, The Powers which perceive the *relations* of external objects. The fourth genus comprises the *Reflective Faculties*, which act on all the other powers; in other words, compare, discriminate, and judge.

We owe to Dr Spurzheim the names of most of the faculties as yet in use; and they have only been ridiculed, on account of their novelty, by those who did not perceive their logical accuracy. In all the propensities we find the termination *ive* to denote the quality of producing—as Destructive. To this is added the syllable *ness*, to denote the abstract state. Instead of *ive*, the termination *ous* is found in the name of a sentiment, with *ness* added—as Conscientiousness—to express the abstract quality. The names of the intellectual faculties require no explanation. The arrangement of the faculties usually adopted is that of Spurzheim, in the third edition of his 'Phrenology.'

The following is a representation of a bust of the human head in four points of view—front, side, back, and top—with the organs marked by numbers:—

ORDER FIRST.—FEELINGS.

GENUS I.—PROPENSITIES.

The propensities here classified and described are common to man and the lower animals.

No. 1.—Amativeness.

This organ (No. 1 on the marked bust) is situated immediately over the nape of the neck, and fills up the space between the ears behind, or rather between the mastoid processes, or projecting bones behind the ears. It generally forms a projection in that part, and gives a thickness to the neck when it is large, and a sparseness when small. The cerebellum, or little brain, is, or at least contains, the organ of this propensity. It was Spurzheim's opinion, that the fact that the cerebellum is the organ of the amative propensity, was supported by a more overwhelming mass of evidence than any other truth known to him. Although Amativeness is the only ascertained function of the cerebellum, it is not impossible, from its size and structure, that it may include the organs of other functions; but no others have yet been discovered.

It is not necessary here to enter fully into the character of this faculty. As the basis of the domestic affections, it is one of great importance, and its regulation has ever been one of the prime objects of moral systems, laws, and institutions. For the evils and calamities, often amounting to national, to which it has occasionally led in its abuse, we need only refer to history. Dr Spurzheim held, with regard to this faculty, that, in education, a more candid and explicit mode of treating it might be advantageous; and much could be said in defence of his opinion.

No. 2.—Philoprogenitiveness.

This, in man as well as animals, is the feeling of the love of his offspring. It depends on no other faculty, as reason or benevolence; it is primitive; and in the female, who, for wise reasons, is gifted with it most strongly, its object, the infant, instantly rouses it to a high state of excitement. It is situated in the middle of the back of the head, and when large, projects like a portion of an ostrich egg. See fig. 3. It is small in fig. 4.

Fig. 3.

Fig. 4.

It was discovered by Dr Gall from its extreme protuberance in monkeys; and we have only to visit a zoological garden to see how that animal cherishes its young. All naturalists are agreed in this as a quality of the monkey species. The organ is one of the easiest to distinguish in the human head. Those who are flat and perpendicular there, instead of being delighted, are annoyed by children. It is generally smaller in males than in females, though sometimes found larger; and men so organised delight to carry about and nurse children. The feeling gives a tender sympathy generally with weakness and helplessness; and we find it often returned by the young themselves to the old and feeble. It is essential to a soft kind attendant on the sick, to a nursery-maid, and to a teacher of youth.

The most savage races may have the impulse to protect their young, or they would become extinct. The organ, like the other cerebral organs, may become diseased; and insanity on the subject of children may be found in many asylums.

No. 3.—Inhabitiveness—Concentrativeness.

The organ is situated immediately above the preceding. Two of the most distinguished phrenologists, Spurzheim and Combe, disagreed about the function of this organ—at least about its whole function. Dr Gall did not discover its function at all; and Dr Spurzheim, observing it large in persons attached to their native place, or any place in which they had long dwelt, called it *Inhabitiveness*. Mr Combe does not disallow to it this function; and certainly man has such a faculty as attachment to place, often so strong as to render it impossible to move him from a particular spot by the most tempting inducements. The purpose of a faculty which prompts men to *settle* instead of roaming, which latter habit is inconsistent with agriculture, commerce, and civilisation, is obvious; *nostalgia*, or home-sickness, is the disease of the feeling. Mr Combe claims for it, however, a more extended sphere of action than love of place—one, at the same time, with which we have always thought love of place may be reconciled. He has observed the organ large in those who can detain continuously their feelings and ideas in their minds, while the feelings and ideas of others pass away like the images in a mirror, so that they are incapable of taking systematic views of a subject, or *concentrating* their powers to bear on one point. The first class of persons, in conversation, continue the same subject till it is exhausted, and pass gracefully to another connected with it: it is painful to converse with the others, whose unconnected thinking gives us the notion of what is vulgarly called *scatter-brains*. We must content ourselves with what is here said, and refer the reader for proofs and arguments, on either side, to the works of Mr Combe and Dr Spurzheim. The organ is stated as only probable, till further facts are obtained.

No. 4.—Adhesiveness.

This organ will be observed on the engraving of the marked bust to be situated on each side of No. 3; a little lower down than No. 3, but a little higher up than No. 2, at the middle of the posterior edge of the parietal bone. It was discovered by Gall, from being found very large, and of the same shape as on the bust, in a lady remarkable for the warmth and steadiness of her friendships; and was observed in so great a number of instances to accompany this propensity, and to be flat or hollow in those who never formed attachments, that he came to consider it as demonstrated. It attaches men, and even animals, to each other, and is the foundation of that pleasure which mankind feel, not only in bestowing, but receiving friendship. Acting in conjunction with Amativeness, it gives constancy and duration to the attachment of the married. Amativeness alone will not be found sufficient for this. Hence the frequent misery of sudden 'love marriages,' as they are called, founded on that single impulse. The feeling attaches many persons to pets, such as birds, dogs, rabbits, horses, and other animals, especially when combined with Philoprogenitiveness. With this combination, the girl lavishes caresses on her doll and on her little companions. Added to Nos. 1, 2, and 3, with which it is in immediate contact and ascertained fibrous connection in the brain, it completes what has been called the domestic group of organs, or the love of spouse, children, home, and the friends of home, as brothers, sisters, cousins, &c. The feeling is strongest in woman. Her friendships, speaking generally, are more ardent than man's. The faculty is not kindness or benevolence; it is instinctive attachment, often felt by those who are selfish in everything else—selfish even in their attachments. It is the faculty which prompts man to live in society; and its existence overturns the absurd theory of Rousseau and some others, that man

## PHRENOLOGY.

is solitary, and that mutual interest alone brings men to congregate with their fellow-men.

### No. 5.—Combattiveness.

The organ of this propensity is situated behind, and a little upwards from, the ear; anatomically, at the posterior-inferior angle of the parietal bone. Compare fig. 5, which is an outline of the skull of General Wurmsler, at the organ 5, with fig. 6, that of a Cin-

Fig. 5.

Fig. 6.

galese, at the same organ. No. 12 is the organ of Cautiousness, to be afterwards treated of. In this the difference is reversed between these two heads. Dr Gall discovered the organ by a vast number of observations on the heads of individuals whom he observed to be addicted to fighting. Dr Spurzheim extended its function to *contention* in general, whether physical or moral. The condition of the physical world, full of difficulties and dangers, seems in itself to make it necessary that man should possess a faculty giving the impulse to meet boldly, and press vigorously through, such impediments. In the mingled scene, also, which forms the moral world, such an impulse is not less needed. It is easy, therefore, to reconcile with our ideas of Divine wisdom and goodness the existence of this vehement quality of our nature, the true intent of which is expressed in the well-known adage of the Mantuan bard—'Ne cede malis, sed contra audentior ito' ['Do not give way to evils, but go the more daringly against them']. A small endowment of this faculty manifests itself in that over-gentle and indolent character which is easily aggressed upon, easily repelled by the appearance of difficulty and trouble, and which naturally seeks the shades and eddy-corners of life. To control and guide the propensity is one of the most delicate, but also most important, duties of the educator. When Combattiveness is deranged, we have a violent and noisy, and often dangerous patient. The organ is held to be established.

### No. 6.—Destructiveness.

This organ is situated on both sides of the head, immediately over the external opening of the ear, extending a little forward and backward from it, and rising a trifle above the top or upper flap of the ear. In fig. 7 the organ is large; in fig. 8 it is small. Dr

Fig. 7.

Fig. 8.

Gall discovered the organ by comparing the skulls of carnivorous with those of graminivorous animals, and afterwards by observing the same prominence in those of several murderers sent him for examination. Though generally considered as giving the impulse to kill and destroy, in man this propensity is shown to have, under the control of the higher sentiments and intellect, a legitimate sphere of exercise. Those roughnesses and difficulties in the physical world which have been shown to call for the exercise of Combattiveness, that man may not sink under them, also appear to call for a faculty which may prompt to the destroying or repressing of them, so that the way may be cleared for the future. The annoyances and troubles of the moral world call in like manner for a faculty which may be always endeavouring to put an end to them. There

are many animate and inanimate things, and many institutions and social arrangements which, though useful for a time, become in the end noxious, and require to be destroyed: the organ under notice appears to be that which is commissioned to do this duty. It prompts beasts and birds of prey to keep down the redundant breeds of the lower animals, and disposes man to 'kill' that he may 'eat.' It dictates the demolition and clearing away of obstructive objects of all kinds, and prompts Luthers and Mirabeaus to the extermination of bad systems. Anger, resentment, and indignation in all their shapes, likewise spring from this faculty. St Paul indicates its legitimate exercise in this class of its manifestations, in the words 'Be ye angry, and sin not.' A small endowment of this faculty is one of the elements of a 'soft' character. Persons so organised seem to want that which gives momentum to human operations, like an axe wanting in back weight. Those, on the other hand, who have a large endowment of Destructiveness, are generally marked by an energetic, and probably fierce and passionate character. If uncontrolled by moral feelings naturally strong, or cultivated into activity by education, they are apt to be violent and vindictive.

### Alimentiveness—Love of Life.

Some of the recent phrenological works treat in this part of the order of the faculties, of a faculty of Alimentiveness, and also of another which follows—namely, Love of Life. The first being yet no more than *probable*, and the second only *conjectural*, they have no number allotted to them on the bust.

*Alimentiveness* is the desire of, or appetite for, food. In this feeling, as such, the stomach is not concerned: its functions are strictly confined to the reception and digestion of our food. But that the mind is concerned in our desire of food, is proved by many circumstances. Were desire anywhere but in the brain, there could be no permanent character in individuals—as the glutton, the epicure, the abstemious. Satisfied that appetite is a mental faculty, phrenologists have long been looking for its organ. Dr Hoppe of Copenhagen was the first to observe in those who manifested remarkably the gourmand or glutton a fulness in front of Destructiveness, in the *fossa zygomatica*, between the top of the ear and the temple. Its place is marked by a cross † on the side view of the bust. Many phrenologists have confirmed this by observation, so that the organ may now be said to be advanced from *conjectural* to *probable*.

The self-preservation involved in the *love of life* is certainly not accounted for by any known organ or combination of organs. Cautiousness is fear of injury, fear of death; but it is not love of life. This feeling is powerfully manifested by some when their life is in no danger, but who look upon the close of life as a very great evil. Others are so indifferent on the subject, as scarcely to care whether they live or die, but for the disagreeable effect the contemplation of death has upon their other faculties—such as leaving children unprovided, &c. Mr Combe thinks that the organ is situated in the base of the middle lobe of the brain, and that its development cannot be ascertained during life.

### No. 7.—Secretiveness.

The organ of this faculty will be observed by its number on the bust, to be situated immediately above that of Destructiveness, at the inferior edge of the parietal bones, or in the middle of the side of the brain. Dr Gall observed this fulness in one of his companions remarkable for *finesse* and cunning, and for his sly expression. He observed it in another companion whose gait and manner were those of a cat watching a mouse. The first companion was honest, and only deceived for sport; the other, however, being deficient in moral restraint, turned out perfidious, and deceived his companions, his tutors, and his parents. An immense number of observations confirmatory of the soundness of Dr Gall's conclusions have led phrenologists to regard this organ as established. The legitimate use of

the faculty is to exercise that control over the outward manifestation of the other faculties which is necessary to a prudent reserve. Without it, and of course in those in whom the organ is small, and the manifestation weak, the feelings express themselves too plainly. Such individuals are too open and unsuspecting, and often all good taste and propriety are lost sight of by them in the exposure of their feelings. We may consider secretiveness as an instinct to conceal the feelings or thoughts, till reason shows it to be prudent to declare them. This control evidently was not left to reason alone, whose judgment would have proved too slow for the end intended. Concealment is given to animals to enable them both to avoid and to prey upon each other.

In abuse, the faculty leads to lying, hypocrisy, and fraud. When acting with Acquisitiveness, it forms the thief, cheat, and swindler. The organ is subject to disease, and the cunning insane are difficult to deal with. Disease here leads to the belief in plots and conspiracies formed against the patient, so common with the insane. The manifestations of Secretiveness ought to be watched in education, and carefully regulated; and the maxim impressed, that cunning is not wisdom.

No. 8.—Acquisitiveness.

The organ of this faculty is situated farther forward than, and a little above, Secretiveness, at the anterior-inferior angle of the parietal bone. The existence of a cerebral organ for the desire of property, bearing a proportion in size to the degree of that desire, decides the question of the feeling being a primitive animal power, and not, as Hutcheson, Stewart, and Brown have held it, the mere result of calculation, wealth being the means of gratifying all our other inclinations. Man feels as an animal before he reasons. Lord Kames, whom the regular metaphysicians of his time considered as admitting too many faculties, takes, by sagacious anticipation—as he did when he recognised a hunting and killing propensity in man, phrenologically Destructiveness—the phrenological view of Acquisitiveness as primitive, and calls it 'the hoarding appetite.' This theory of it alone explains the miser's desire to accumulate, without ever putting his wealth to the use required by the metaphysicians above named, the purchase of enjoyment, the gratification of the other faculties. The faculty of Acquisitiveness could not, and no faculty could, be given to man by his Creator for any mean, grovelling, and immoral purpose; accordingly, when we consider it aright, we recognise in it the dignity of the greatest utility. In a word, it is the faculty through whose impulse man accumulates capital, and nations are rendered rich, great, and powerful. Without the faculty, man would be content to satisfy his daily wants, although even in this he would fail; but the surplus which, under the impulse of this faculty, he contributes to the store of wealth which accumulates from generation to generation, would not exist. Under proper regulation, then, the faculty is of the greatest value to man; by means of it he 'gathers up the fragments, that nothing may be lost.' Excessive pursuit of wealth is, however, an abuse of the faculty, and too much the vice of civilisation, when it advances, as it has hitherto done, without adequate moral improvement.

The organ is often diseased; so that those who are insane in this faculty, without any temptation arising from their circumstances, which are often above want, and even prosperous, pilfer everything of value, and often of no value, which comes in their way. Again, many incorrigible thieves in lower life, on whom the punishments of the law fail to have any effect, are diseased in this organ. Phrenology thus demonstrates that many supposed criminals are in truth patients, and ought to be treated as such.

No. 9.—Constructiveness.

The situation of this organ is in the fore part of the temples, at the frontal bone, above the sphenotemporal suture. It is sometimes found higher up than its usual

position; but a little practice familiarises the observer with its appearance. The faculty of which this organ is the instrument, is the power of mechanically making, and constructing, by changing the forms of matter. Many of the inferior animals possess it; as the bee, birds, and insects. Some savages have it in such measure, as never to have built huts or made clothes, or even the simplest instruments for catching fish. Such are the New Hollanders, in whom the organ appears very slightly developed. Drs Gall and Spurzheim verified this organ by a vast number of instances—in mechanics, architects, designers, sculptors, and even painters. Metaphysicians do not recognise a primitive faculty of Constructiveness, but consider mechanical skill to be the result of reason. This is an error which the slightest observation contradicts. Were it true, say the advocates of phrenology, the most sagacious animals would be the most constructive; yet the horse, the dog, the elephant, never construct; while the bee, the beaver, and many birds and insects, perform works by this instinct which excite our wonder. Very young children, long before reason could assist them, have manifested proficiency in making models, drawing, cutting with scissors, &c. Even idiots are often skilful constructors, witness many of the Crétins of the Alps. Intellect is, however, important to the range, variety, and application of human Constructiveness; while the Constructiveness of the inferior animals is limited to one invariable result.

The use of this faculty is obvious. Physical nature consists of raw material, in scarcely any instance fitted for the convenience and accommodation of man. Constructiveness prompts him to form and fashion; and he continues to do so, advancing—which the inferior animals never do—from building the rude wigwam and making the stone-hatchet, up to achieving the palace, the steam-engine, and the spinning machine.

GENUS II.—SENTIMENTS.

Mr Combe introduces this branch of the subject thus:—'This genus of faculties embraces certain feelings which correspond to the "emotions" of the metaphysicians. They differ from intellectual perception in being accompanied with a peculiar vividness, which every one understands, but which it is impossible to express by any verbal definition. They may be excited by the presentation of the external objects naturally related to them, as danger is to fear, or august appearances to reverence, or by the spontaneous activity of the organs. Dr Spurzheim has named these faculties *Sentiments*, because they produce an emotion or feeling of a certain kind, joined with a propensity to act; but, as shown in the Appendix No. II., the detail of his classification is here by no means accurate. Several of them are common to man and the lower animals; others are peculiar to man. The former, styled the Inferior or Lower Sentiments, shall be first treated of.' The argument referred to by Mr Combe in his appendix, is an abridgment of a paper by Mr Robert Cox, in the 'Phrenological Journal' (vol. x. p. 154), in which he endeavours to show that, on the one hand, several of the propensities are accompanied by emotions, as well as inclinations to act, and on the other, several of the sentiments have likewise both qualities.

I. SENTIMENTS COMMON TO MAN AND THE LOWER ANIMALS.

No. 10.—Self-Esteem.

The situation of this organ is at the top of the back of the head, at the centre; forming, as it were, the curve or turn between the back and top of the head. When it is large, the head rises far upward and backward from the ear, in the direction of the organ. It is large in fig. 9, and small in fig. 10. The legitimate use of the faculty of Self-Esteem is that degree of self-complacency which enhances the pleasures of life, and which gives the individual confidence in his own powers, and leads him to apply them to the best

advantage. It is sometimes called proper pride, or self-respect, in which form it aids the moral sentiments in resisting temptations to vice and self-degradation: this is called being *above* doing a criminal, a

Fig. 9.

Fig. 10.

vicious, or a mean action. Its deficiency renders an individual too humble, and the world takes him at his word, and push him aside. In large and uncontrolled endowment, it produces great abuses, and causes much annoyance and often misery to others. In children it is pettishness, frowardness, and self-will, and produces disobedience. In adults it gives arrogance, superciliousness, and selfishness. In nations, the feeling shows itself in national pride and boasting. This produces contempt of other nations, and leads to international jealousies and hatreds, the origin of almost all the wars that have disgraced and desolated the world. Self-Esteem occupies the individual so intensely with self, that he is insensible to all interests but his own; everything is seen by him through the medium of self. The first thought, when a proposal is made, is, 'How will this affect me?' Love of Approbation is often useful by subjecting the individual to some degree of dependence on the opinion of others, to moderate the intensity, the exclusiveness, of Self-Esteem. Without this counterpoise, the self-esteeming person becomes a self-erected standard of opinions, manners, and morals. Discussions of character, with vilifying remarks, come from a large Self-Esteem, and that want of candour and fairness which is the result of an inferior endowment of Conscientiousness. Envy, which includes hatred, is Self-Esteem rousing Destructiveness; with deficient Benevolence and Conscientiousness, the envious could injure a fortunate individual merely because of his better fortune. It is a modification of invidiousness, although directed against things, and not persons, to affect to undervalue everything one sees—in other words, never to seem pleased—in order to reap from this petty exhibition a fancied consequence, extremely gratifying to a large and active Self-Esteem. A large development of the organ renders its possessors what is called *touchy*—impatient of reproof, and irritated by it, however just, as if it were a positive injury. A small endowment of the faculty is exceedingly rare.

Self-Esteem has a marked natural language. When powerful, the head is carried high, and reclining backwards, an attitude well known to stage kings and lords. The manner is cold, haughty, and repulsive; and two self-esteeming persons meeting, repel each other like the contrary poles of magnets. Dr Reid and Mr Stewart acknowledge this sentiment under the name of the Desire of Power. Dr Thomas Brown calls it Pride. It is evident that these are narrow and partial views of the feeling—one or two only of its manifestations. The organ and feeling are apparently possessed by some of the inferior animals, such as the turkey-cock, peacock, horse, &c. Lord Kames observed that the 'master-ox' must have the lead, else he will not work. Self-Esteem is found insane perhaps more than any other faculty, and then shows itself in extravagant notions of self-importance. Such maniacs are kings, emperors, and even the Supreme Being. The organ is generally larger in men than in women; and more men are insane from pride than women.

## No. 11.—Love of Approbation.

This organ is situated on each side, close to Self-Esteem, and commences about half an inch from the lambdoidal suture. It gives, when large, a marked fulness to the upper part of the back of the head. The faculty is the desire of approbation, admiration, praise, and fame. Its legitimate function is regard to reputation and character, and it gives the sentiment of shame. It is an excellent guard upon morals as well as manners. The loss of character, to those largely endowed with this feeling, is worse than death. If the moral sentiments be strong, this sentiment will desire honest fame, and in the line, too, of the prevailing faculties—as poet, painter, orator, warrior, statesman. The love of glory is a passion with many, and has deluged the world with blood in all ages. The decorations, orders, stars, garters, of civilisation, and the tattooing, nose-boring, and pluming of savage life, all spring from Love of Approbation. When the propensities predominate, the vain man will be pleased to be thought the best fighter or greatest drinker among his acquaintance. A due endowment of this faculty is essential to an amiable character. 'It gives,' says Mr Combe, 'the desire to be agreeable to others; it is the drill-sergeant of society, and admonishes us when we deviate too widely from the line of march of our fellows; it induces us to suppress numberless little manifestations of selfishness, and to restrain many peculiarities of temper and disposition, from the dread of incurring disapprobation by giving offence; it is the butt upon which wit strikes, when, by means of ridicule, it drives us from our follies.' What the world will think and say, is uppermost in the mind when Love of Approbation is too strong. A youth in whom it is powerful, cannot do this thing or the other because everybody will look at him, or wonder at him. The young are extremely sensitive on this point, especially in relation to those of their own age. The admonitions of the parent or teacher are nothing with them in comparison with the jeering of their companions. Ridicule is intolerable to a large Love of Approbation at any age. Hence the poet's thought, 'the world's dread laugh which scarce the stern philosopher can scorn.' Combined with Self-Esteem, it creates the impression that the world are all busy thinking of us, instead of themselves; which last is the truth. This excess of the feeling subverts all independence. The opinion of others is the unhappy individual's rule of morals, taste, religion, even philosophy. As this faculty, and that of Self-Esteem in abuse, are the cause of much evil, both to the individual and others, education ought to endeavour to moderate their activity.

The faculty, unless kept in subordination by a very large and vigilant Conscientiousness, prompts to all the conventional insincerities and flatteries of society, from the dread that the truth will offend Self-Esteem, and draw down on the teller of it disapprobation. When Secretiveness is large, and Conscientiousness small, Love of Approbation is profuse in the unmeaning compliments of society. These compliments many people scorn only when applied to others, but take more complacently when addressed to themselves; their Self-Esteem supporting them, and persuading them that these compliments *have* a meaning, and value too, when *they* are the objects of them. Much of the acutest suffering of life consists in nothing else but wounded Love of Approbation.

Shamelessness is the effect of the want of this faculty, often observed in criminals. It is a great defect in character; the individual is beyond the salutary government of the feeling; he cares not for the opinion of others, and laughs equally at their censure or approbation. The educator finds this negation very difficult to deal with, inasmuch as one engine, with which he might otherwise legitimately work, is useless to him. His pupil will not *draw* by Love of Approbation. This defect aids the impudent, who have a purpose to serve. Their importunity is often boundless and untiring. No

repulses affect them, no indignities touch them, so long as absolute personal violence is not applied to their intrusions. The *blush* is the natural language of shame—one of the feelings of powerful and sensitive Love of Approbation. The organ is oftener found insane in women than in men, as in women it is more active than in the other sex generally. The patients whose Love of Approbation is diseased, are not solemn, haughty, and irascible, like the monarchs of Self-Esteem. They are generally in a bustle of display, overpowering the listener with details of their merits, their talents, their works, and even their beauty.

No. 12.—Cautiousness.

The organ of this faculty is situated about the middle of the parietal bone on both sides. Dr Gall discovered it by first observing the prominence large in two individuals who positively harassed him with their doubts, fears, hesitations, and precautions. When he observed this cerebral mark for the peculiarity, he confirmed it by numberless subsequent observations. No organ is more easily observed than Cautiousness. It is evident to the eye as well as to the hand, and there is none of which the concomitant mental feeling may be predicted with greater confidence.

It has been said that *fear* is the fundamental feeling of this faculty: we doubt this. Fear is a disagreeable affection of the faculty, for it is one of its feelings, and we are disposed to think that the disagreeable or painful is not the root of any of our faculties. We are not necessarily conscious of the feeling of fear while we are taking the most circumspect precautions for our safety, and it is just when we have taken these precautions that fear is excluded. In our opinion, Cautiousness expresses the feeling better than Fear. The words *foresight* or *circumspection* are too intellectual for it; for it does not foresee or look around; it merely feels blindly, and stimulates the intellect to take the means of insuring safety: its motto is, 'Take care.' It is an important element in prudence, which places the individual on his guard, and warns him not to be rash in his moral, as well as his physical movements. In general, the organ is large in children—a wise and beneficent provision for their self-protection.

The symptoms of a very large endowment will be timidity, fears, and even imaginary terrors, especially in dreams. The organ is often diseased, and then produces causeless dread of evil, despondency, and often suicide. In the heads of suicides the organ is usually large, and Hope deficient, Destructiveness also being of course large. Persons with the organ diseased will often shrink, as if the house were about to fall over them, or a bridge under them. Those who do not distinguish feeling from thinking, imagine that such persons may be reasoned into a dismissal of their fears, on being shown that they are groundless; but if, as is demonstrable, the feeling results from a portion of brain being positively diseased, it would be as rational to attempt to reason a person out of the pain he suffers from a bodily wound or sore. The effect of fear, or sudden and violent excitement of Cautiousness, in producing mental derangement, and all sorts of nervous disease, is well known. Practical jokes, harmlessly intended to frighten, have often fearfully overshot their aim, and produced lasting insanity.

II. SUPERIOR SENTIMENTS, PROPER TO MAN.

We have hitherto considered the faculties which phrenologists describe as common to man and the lower animals; we are now to treat of those superior sentiments which they consider as peculiar to man. The organs of these sentiments lie in the superior region of the brain. That they are all of them entirely wanting in animals, is an opinion which the phrenologists will yet, probably, have to reconsider; but we deem it best in the meantime to follow the generally received view. It may only be remarked, that while the convolutions of the brain which form Veneration, Conscientiousness, and Hope, are not found in animals,

traces of the convolutions forming Benevolence and Imitation do appear; and these two last are the powers of this class with which it seems most likely that animals are endowed.

No. 13.—Benevolence.

The organ of this sentiment is situated at the upper part of the frontal bone, immediately before the fontanel, in the middle of the top of the forehead, where it turns to form part of the top of the head, or coronal surface. It is easily distinguished; and when large (see fig. 11), gives a round elevated swell to that region. When the organ is small (fig. 12), the forehead or top-front is low, flat, and retreating. We cannot blame the

Fig. 11.

Fig. 12.

unfortunate individual so organised, seeing that he did not make himself; but we are so constituted as instinctively to shrink from him, as deficient in one of the chief ornaments of human nature—the faculty of kindness and brotherly love.

The faculty of Benevolence gives more than compassion for, and a desire to relieve, suffering; it gives a wish that others should be positively happy; prompts to active, laborious, and continued exertions; and, unless Acquisitiveness be very large and powerful, to liberal giving to promote its favourite object. It differs essentially in its charity, 'which suffereth long, and is kind,' 'and vaunteth not itself,' from that which springs from Love of Approbation. Yet to this last selfish faculty how often is it necessary to appeal when funds are wanted for benevolent purposes! Hence the *published* lists of subscribers' names; hence, too, the appeals to other selfish faculties by balls, plays, &c. for contributions to relieve suffering, as if it were to be charmed away by dancing and music. The Samaritan's conduct was pure benevolence. The faculty, like sunshine, lights as well as warms the whole of social intercourse. Those who have the organ small are not on that account cruel; for cruelty is the result of a positive faculty—Destructiveness: they are merely indifferent to others' suffering, so that their Destructiveness meets with no check. Hare the murderer was an example. He required no effort, no drowning influence of liquor, as even the wretched Burke did, to steel him against the cries and struggles of his victims. See his head, fig. 2, contrasted with a benevolent development, fig. 1. Benevolence is the chief ground of an individual's popularity; when added to integrity and talent, it renders a public man justly an idol. The martial fame of Henry IV. of France has descended in the mild company of the history of his benevolence; and his memory is yet, after nearly three centuries, dear to the French people. The air that bears his name is the first they call for in their theatres. Unregulated by Conscientiousness and Intellect, Benevolence degenerates into abuse, and becomes profusion and facility. Such an endowment gives indiscriminate alms, without reflecting that it is thereby probably encouraging fraud and crime. When Conscientiousness is weaker than Benevolence, we see the individual generous before he is just—making expensive presents, and leaving his tradesmen unpaid. Benevolence often coexists with Destructiveness, although this has been denied as an inconsistency in nature. How many individuals known to us are at once kind-hearted and hasty and irascible!

No. 14.—Veneration.

The organ of this faculty occupies the centre of the coronal region just at the fontanel—the centre of the top of the head. It was discovered by Dr Gall in the

## PHRENOLOGY.

pious and devout; and is very obvious in the bald head of the monk of real sentiment and not of mere interest. The function of the faculty is the sentiment of veneration, or deference in general for superiority, for greatness, and goodness. Its highest object is the Deity. It is remarkable in how many instances the painters of sacred subjects have given large development of this organ in the heads of their apostles and saints—no doubt because the pious individuals whom they would naturally select as studies for such characters possessed the organ large. Veneration has no especial object: it finds appropriate exercise with regard to *whatever is deemed superior*. One man may venerate what another treats with indifference, because his understanding leads him to consider that particular object as superior, while his neighbour deems it upon his own level, or beneath it. But any man with a large endowment of the organ will have a tendency to consider things as superior: he will be naturally disposed to look up, and not to look down. Self-Esteem is a positive faculty opposite to Veneration. The one prompts to a regard for, and appreciation of, self; the other to a regard for, and appreciation of, others, or something above self. He in whom there is much Veneration, with a moderate or defective Self-Esteem, will always be disposed to think well of what other persons do, and to put himself under their guidance and advice, which he will scrupulously follow, although his own understanding might have suggested better courses. Veneration is the basis of the feeling of loyalty: it is a main element in such political parties as the Jacobites of England and the Carlists of France. We see it irrationally exercised in the savage with regard to his idols of stone and wood, and in civilised society with regard to the mere idea of rank unattended by worth. It is, on the other hand, rationally exercised with regard to persons of real excellence, and those who have been invested with important functions for the benefit of society.

Veneration, having the Deity for its highest object, forms an element in the purest and most exalted religious feeling. But while there can be no perfectly pious man without it, we are bound to admit that individuals are often found passing for very fair religious characters, in whom Veneration is by no means conspicuous. Such show little reverence or care in the handling of Divine things, and often address the Deity in their prayers in a style calculated to shock others by its familiarity. So liable is the organ of Veneration to disease, that devotional exaltation is well known to be one of the most common forms of insanity. The religiously insane abound in the asylums. Drs Gall and Spurzheim adduce many examples, and in all of them the organ of Veneration was found large.

### No. 15.—Firmness.

The organ of this faculty occupies the top of the head, behind Veneration, in the middle line. It is a faculty of peculiar character. Dr Gall held that it was neither an inclination nor a power, but a *manière d'être*—a mode of existing or being firm, resolute, and determined. He who is deficient in the faculty is the sport of circumstances and impressions. Dr Spurzheim says that Firmness is apt to be mistaken for Will, because those that have the organ large are prone to say 'I will,' and 'I wont,' that being the natural language of determination; but the feeling is quite different from what is properly called the Will. It gives fortitude, constancy, perseverance, and determination; and when too powerful, it produces obstinacy, stubbornness, and infatuation. The organ will be found large in obstinate and intractable children. Firmness has no relation to external objects; its influence is within the mind, and adds a quality of endurance to each or all of the other faculties. For example, it renders Combativeness determined bravery; Conscientiousness inflexible integrity; and so with others. With Self-Esteem it renders the individual absolutely impracticable. The want of it is a great defect in character: it is unsteadiness of purpose. Fig. 13 is that of the head of a lady who had

several houses taken because she could not *determine* in which she should live: her Conscientiousness (marked 16) will be observed large, and this feeling she manifested by faithfully and punctually paying the rents of

Fig. 13.

Fig. 14.

them all. The English soldier has more of Firmness than the French, although in courage and spirit they are equal. The organ is large in the torture-enduring American Indian. In fig. 14 it is small; in 13, large.

### No. 16.—Conscientiousness.

The organ of this sentiment is situated on each side of the organ of Firmness, between the latter organ and that of Cautiousness. Dr Spurzheim discovered the organ, and thereby incalculably benefited mental and moral science. Previously, metaphysicians differed in opinion as to the existence of a moral sense—a primitive instinctive feeling of truth and justice. Hobbes and Mandeville held justice to be mere selfish calculation. Even Paley considered it as influenced by the hope of eternal reward, and therefore no better than a selfish calculation. Adam Smith placed the standard of moral approbation in sympathy, Hume in utility, Clarke in the fitness of things; while Hutcheson, Cudworth, Kames, Reid, Stewart, and Brown all contend for a *faculty* which produces the sentiment of right and wrong, independently of all other considerations. Without this faculty, the sentiments which guard, or rather constitute, morality, would be incomplete. Benevolence prompts to kindness, and is offended with cruelty; Veneration induces piety, and is shocked with blasphemy; but neither of these faculties gives the perception or feeling of obligation, duty, incumbency, truth—in a word, justice. When, however, Conscientiousness is superadded, the defect is supplied, and morality completed—that morality which Scripture recognises in the precept 'to do justly, to love mercy, and to walk humbly with God.'

Conscientiousness gives the emotion of justice, but intellect is necessary to show on which side justice lies. The judge must hear both sides before deciding, and his very wish to be just will prompt him to do so. This faculty regulates all the other faculties by its rigid rules. It says to them, 'thus far and no farther, or you will do injustice.' Benevolence and Veneration themselves require its guardianship, to prevent the one from running into generosity without justice, the other into bigotry, fanaticism, and persecution. Conscientiousness not only curbs our faculties when too powerful, but stimulates those that are too weak, and prompts us to duty even against strong inclinations. To cultivate it in children is most important. No organisation, however favourable, compensates a want here; yet phrenologists are forced to confess that it is not the largest organ in the great majority of brains, and hence the injustice that is, silently, as well as openly, at work in society. The training of it by practical exercise in infant education is explained in the volume on 'Infant Education' in *Chambers's Educational Course*. Conscientiousness not only prompts to honesty and truth, in opposition to common fraud and falsehood, but, more delicately still, renders the individual who is blessed with it in large measure candid and fair in his judgments of the conduct, opinions, and talents of others. It pays debts, keeps appointments, performs promises, and gives a beautiful consistency and trustworthiness to the whole conduct, which secures the respect, and when blended with Benevolence, the love, of

all within the range of its influence. Without Benevolence, it is apt to be too severe and stringent. When Conscientiousness is weak, or when, as happens in perfectly 'honest' and 'honourable' people, in the broad sense of these terms, it is not something more than average in its power, the defect will run through the whole conduct and judgments of an individual. We often hear people complaining that a particular friend is 'uncertain.' This word expresses concisely the defect of Conscientiousness above described.

The existence of Conscientiousness as an independent element in the human constitution, renders intelligible many supposed inconsistencies in human conduct—that a man, for instance, will be kind, forgiving, even devout, and yet not just. It is a great mistake with regard to those who, after many years of sanctimonious professions, are detected in dishonest acts, to say that they must have been all along mere hypocrites. It is quite possible that many of their religious feelings and convictions may have been sincere, but only insufficient in force to compensate for the lack of direct Conscientiousness. Conscientiousness gives remorse when the individual has been tempted to sin. The organ is larger in some nations than others. It is larger generally in Europeans than in Asiatics and Africans; very generally it is deficient in the savage brain. It evidently grows in civilisation; indeed, it constitutes an essential of civilisation. The organ is often found diseased, and the insanity consists in morbid self-reproach, imaginary debts, and unfounded belief in merited punishment.

No. 17.—Hope.

The organ of this faculty has its place on each side of Veneration, partly under the frontal, and partly under the parietal bone. It was discovered by Spurzheim, but never admitted by Gall, who considered Hope as a function of every faculty that *desires*. To this Dr Spurzheim answered, that we desire much of which we have no hope; a criminal on the scaffold intensely desires life, but has no hope of it. Dr Spurzheim considered Hope a faculty *sui generis*, producing hope, in general, of good, or gratification to the other faculties; and, by careful observation in nature, found the organ in the situation just described. It seems to have been given to man to make him happy. It produces gaiety and cheerfulness, looks on the sunny side of everything, and paints the future with bright colours. When not regulated by the intellect, Hope leads to rash speculation, and, in combination with Acquisitiveness, to gambling, both at the gaming-table and in the counting-house. It tends to render the individual credulous, and often indolent.

No. 18.—Wonder.

The organ of this faculty is situated on each side of that of Benevolence, with one other organ, that of Imitation, interposed. Dr Gall discovered it by observing it large in the seers of visions and dreamers of dreams, and in those who loved to dwell on the marvellous. Persons with the faculty powerful are fond of news, especially if striking and wonderful, and are always expressing astonishment; their reading is much in the regions of the marvellous, tales of wonder, of enchanters, ghosts, and witches. When the sentiment is excessive or diseased, it produces that peculiar fanaticism which attempts miracles, and with Language active, speaks with unknown tongues. It draws the ignorant and fanatically-inclined, who have the organ large, with ease by its pretensions; hence the numerous followers of Johanna Southcote, Thom, and Edward Irving. Mr Combe says of the last—'I examined his head before he was established as a preacher, and when his peculiarities were unknown, and observed that the organs of Wonder and Self-Esteem were very large. They gave a tinge to his whole public life. The organs of Benevolence, Conscientiousness, Veneration, and Intellect were also amply developed, so that he possessed the natural elements of the Christian cha-

racter in great strength, but their direction was rendered unprofitable by the predominance of Wonder and Self-Esteem.' The general function of the organ is held to be ascertained, but the metaphysical analysis is still far from being perfect.

No. 19.—Ideality.

The organ of this faculty is situated farther down, but close to that of Wonder, along the temporal ridge of the frontal bone. Dr Gall discovered it in the busts and portraits of deceased, and in the heads of a great number of living, poets. This confirmed to him the old classical adage, that the poet is born, not made; in other words, that his talent is the result of a primitive faculty. Dr Gall called it the organ of Poetry. Dr Spurzheim corrected this, and gave it the elegant name it now bears; which has, as well as others of the expressive names of the phrenological organs, been adopted into ordinary language.

The faculty delights in the perfect, the exquisite, the *beau-ideal*—something beyond the scenes of reality—something in the regions of romance and fancy—of the beautiful and the sublime. Those writers and speakers who possess it large adorn all they say or write with its vivid inspirations. It is the organ of imagery. The sermons of Chalmers owe much of their charms to it, and the organ was very large in his head. Shakespeare created such beings as Ariel, Oberon, and all the imaginings of the 'Tempest' and 'Midsummer Night's Dream,' under its influence. The faculty renders conversation elevated, animated, and eloquent.

Nature abounds in beauty and splendour to gratify Ideality—a proof of pure beneficence in the Creator; for it is a pleasure of unmixed gratuity, if we may so speak: man might have been created without it; but Divine goodness superadded that, the most exquisite, to his other enjoyments. The organ is small in criminals and other coarse and brutal characters, for it is essential to refinement. It prompts to elegance and ornament in dress and furniture, and gives a taste for poetry, painting, statuary, and architecture. A point of interrogation is placed on the bust on the back part of the region of this organ, conjectured to be a different organ, but one allied to Ideality. Some phrenologists have considered it the organ of the Sublime, from its touching on Cautiousness, which the grand, at least the terrific grand, in some degree affects. A writer in the 'Phrenological Journal' suggests the love of the past as its function. The existence of the faculty of Ideality demonstrates that the sentiment of beauty is an original emotion of the mind, and settles the controversy in which Professor Stewart, Lord Jeffrey, Dr Brown, and others took a part, as to the origin of our perception of beauty. The organ is held as established.

No. 20.—Wit, or the Ludicrous.

The organ of this faculty is situated before, and a little lower than that of Ideality. When large, it gives a breadth to the upper region of the forehead. In the portraits of Sterne, his forefinger is represented resting on this angle of the forehead, which in him was very large, and the mental manifestation powerful.

The phrenological writers have discussed at great length, and with not a little controversy, the metaphysical nature or analysis of this faculty. We do not require to follow them into this inquiry, as most of them are agreed that by means of this faculty we see and enjoy the *ludicrous*, and experience the emotion of laughter. Man is the only laughing animal, and the impulse and its result are too well-marked characteristics not to be the manifestations of a special faculty. Dr Beattie's theory is the most satisfactory of any—that the objects of the ludicrous are incongruities, with a certain mixture of congruity. When this organ is large, the individual both enjoys and creates the ludicrous, and is apt to give a ludicrous turn to everything that passes through his mind. For the discussions in which Mr Scott, Mr Watson, and Mr Schwartz of Stockholm have taken a part, as well as for the opinions of Gall,

Spurzheim, and Combe, we must refer to Mr Combe's 'System' (4th edition, p. 416). We may observe that Mr Scott and Mr Hewett Watson consider the organ No. 20 as that of an intellectual, and not an affective faculty. Mr Scott views it as the faculty by which we discriminate or observe differences; and this, by much ingenious reasoning, he is inclined to hold to be the function of a different faculty from that by which we perceive resemblances. Mr Watson thinks the function of No. 20 is to investigate what may be called intrinsicalities—the intrinsic nature of things. Mr Combe thinks the facts adduced by Mr Watson make it probable that there is a faculty for this power, but that it is not No. 20. Dr Spurzheim unsettles both Mr Scott's and Mr Watson's theories anatomically, by showing that the portion of brain is in the same region with Ideality, and is therefore the organ of an affective, and not an intellectual faculty. He farther holds, that the same faculty which perceives resemblances perceives differences; and both he and Mr Combe, observing that all those who deal largely in the ludicrous have the Organ 20 large, conclude, that whatever may be the object or objects of the ludicrous in nature—whether something specific, like colour or odour in a rose, or some condition of things, which in themselves are not necessarily ludicrous—there is a mental sentiment or emotion which excites to laughter. No. 20 is the organ essentially of this emotion, and so far they hold it established.

#### No. 21.—Imitation.

This organ is situated on each side of that of Benevolence. Dr Gall found the protuberance accompanied by instinctive, and often irrepressible mimicry. The purpose of the faculty is to enable the young to learn from the more advanced, and keep a convenient uniformity in the manners and externals of society. Celebrated players always possess it largely, and by it imitate the supposed manner, and even feel the sentiments, of their characters. The Imitative arts depend on this faculty; and its organ is found large, accordingly, in painters and sculptors of eminence. What a fund of amusement and delight comes from the group of faculties whose organs are all in this one region of the head, well named 'The Post's Corner'—namely Ideality, Wonder, Imitation, Wit or the Ludicrous, Time, and Tune! The faculty of Imitation has been recognised in a state of disease when the impulse to mimic is beyond the individual's control. Pinel makes mention of an idiot girl who was affected in this way. Parrots, monkeys, and the mocking-bird imitate and mimic. The last-mentioned often attracts other birds by the cries of their own kind; and then waggishly, as it were, scares them away with the cry of some bird they dread. The organ is established.

#### ORDER SECOND.—INTELLECTUAL FACULTIES.

By these faculties man and animals perceive or gain knowledge of the external world, and likewise of their own mental operations. The object of the faculties is to know what exists, and to perceive qualities and relations. Dr Spurzheim divided them into three genera:—1. The External Senses; 2. The Internal Senses, or Perceptive Faculties, which procure knowledge of external objects, their physical qualities and relations; 3. The Reflecting Faculties.

#### GENUS I.—EXTERNAL SENSES.

By these, man and the inferior animals are brought into communication with the external material world. Much metaphysical scum has been wasted, and much nonsense written, about the senses. Before phrenology discovered internal faculties, of which the senses are the ministers—they themselves giving only passive impressions called sensations, but forming no ideas—the senses were considered the sole sources of our knowledge. They are necessary to that knowledge, but would never of themselves have completed it. By each sense we discover some quality of material nature.

The senses, as generally received, are five in number—Touch, Taste, Smell, Hearing, and Sight. There are certainly two more—namely, the sense of Hunger and Thirst, and the Muscular Sense, or that by which we feel the state of our muscles as acted upon by gravitation and the resistance of matter. Without this last sense we could not keep our balance, or quit our movements to the laws of the mechanical world. Dr Thomas Brown conjectured this sense many years ago, and Sir Charles Bell has thrown much light on it by proving that separate roots, afterwards joining in one apparent nerve, but evidently being two, gave muscular motion and muscular sensation. For further information on this subject, see the preceding sheet.

#### GENUS II.—INTELLECTUAL FACULTIES, WHICH PROCURE KNOWLEDGE OF EXTERNAL OBJECTS, OF THEIR PHYSICAL QUALITIES, AND VARIOUS RELATIONS.

These faculties correspond in some degree with the perceptive powers of the metaphysicians, and form ideas.

#### No. 22.—Individuality.

The organ of this faculty is situated in the middle of the lower part of the forehead, immediately above the top of the nose. It takes cognisance of individual existences—of a horse, for example. Other knowing faculties respectively observe the form, colour, size, and weight of the horse, but a faculty was necessary to unite all these, and give the individual idea of a horse. It furnishes the substratum which has form, colour, &c.—an old desideratum of the metaphysicians. Individuality is the storehouse of knowledge of things that simply exist. It is often large without being accompanied by reflecting power; when this is the case, the individual has been compared to an encyclopaedia, full of facts, but unable to reason from them. All the objects of Individuality are *noun substantives*. Verbs and adjectives are the perceptions of other faculties to be afterwards noticed. As Individuality merely observes existences, without regard to their modes of action, it is the faculty of the naturalist. Those who possess it large and active, observe the minutest objects; nothing escapes them, and they remember even the minutest objects so well, that they will miss them when taken away. On the contrary, those who have it small, observe nothing, and give the most imperfect account of the objects which have been in their way. In the artist, the faculty gives great minuteness of detail, and with Imitation and Form, great power of hitting likenesses in portrait-painting. The faculty prompts to personification of abstract ideas—as Fame, Envy, Wisdom, Folly. The organ is established: the metaphysical analysis of the faculty requires farther inquiry.

#### No. 23.—Form.

This organ is situated on each side of, and close to, the *crista galli*, and occupies the space between the eyes. In those who have it large, the eyes are wide asunder, and *vice versâ*. Dr Gall discovered the organ in persons remarkable for recognising faces after long intervals, and although perhaps only once and briefly seen. The bust of George III. furnishes the best example in the Phrenological Society's collection; and it is well known that he never forgot a face. Townsend, the famous Bow Street officer, had the same talent, one most essential to his office. As every material object must have a form, regular or irregular, this faculty was given to man and animals to perceive forms, and they could not exist without it. When large, it constitutes an essential element in a talent for drawing, but requires Size and Constructiveness to perfect the talent. Forms are capable of great beauty, and of affording much pleasure, and in nothing more than in the human figure. Many persons who have the organ of Form large, connect their words and ideas with forms, and these often fanciful and of their own creating. Mineralogists and crystallographers generally possess this power in large endowment. The celebrated Cuvier owed much of his success in comparative anatomy to his large organ

of Form. Decandolle mentions, that 'his (Cuvier's) memory was particularly remarkable in what related to forms, considered in the widest sense of that word; the figure of an animal seen in reality or in drawing, never left his mind, and served him as a point of comparison for all similar objects.'

No. 24.—Size.

Every object has size or dimension. Hence a faculty is necessary to cognize this quality. The supposed organ is situated at the inner extremities of the eyebrows, where they turn upon the nose. A perception of Size is important to our movements and actions, and essential to our safety. There is no accuracy in drawing or perspective without this organ. Sir George Mackenzie thinks that the faculty of Size, as it cognizes dimension of every kind, whether in length, breadth, thickness, height, depth, or distance, is that faculty whereby we perceive *space* in general, analogous to the faculty of Time, by which we perceive time. Different individuals manifest different degrees of the power of perceiving size. Some seem not to possess the power of estimating distance or dimension, while others can draw a circle without compasses, and find the centre of one already drawn with the greatest accuracy.

No. 25.—Weight.

Weight is a quality of matter quite distinct from all its other qualities. The weight of any material object is only another name for its degree of gravitating tendency—its attractibility to the earth. A power to perceive the different degrees of this attraction is essential to man's movements, safety, and even existence. There must be a faculty for that perception, and that faculty must have a cerebral instrument or organ. Phrenologists have generally localised that organ in the super-orbital ridge or eyebrow, immediately next to Size, and farther from the top of the nose. But as yet the function of the Organ 25 has given rise to so much discussion, as to leave it far from certain what that precisely is. Mr Combe says, 'Persons who excel at archery and quito, and also those who find great facility in judging of momentum and resistance in mechanics, are observed to possess the parts of the brain lying nearest to the organ of Size largely developed; and the organ is now regarded as probable. Persons in whom Individuality, Size, Weight, and Locality are large, have generally a talent for engineering, and those branches of mechanics which consist in the application of forces; they delight in steam-engines, water-wheels, and turning-lathes. The same combination occurs in persons distinguished for successful feats in skating, in which the regulation of equilibrium is an important element. Constructiveness, when Weight is small, leads to rearing still-fabrics, rather than to fabricating working machinery.' Mr Simpson has given much attention to this faculty ('Phrenological Journal,' vol. ii. p. 412), and opened up some original views for discussion in the phrenological world; a new chapter, as Mr Combe calls it, in the science of mind. He cites a number of noted mechanicians and engineers in whom the Organ 25 is large. In the bust of James Watt it is particularly prominent. Children who walk early and steadily have uniformly the organ large, and the inference was drawn that the faculty gives the power of preserving equilibrium, or that balance of forces which is essential to the application of animal power, and even to existence.

No. 26.—Colouring.

As every object must have a colour in order to be visible, it seems necessary that there should be a faculty to cognize this quality. The organ is the next outwards from Weight in the eyebrows, occupying the precise centre of each eyebrow. A hollow there, into which the end of the finger could be put, or such a flatness in the ridge of the eyebrow that a perpendicular line dropt from it would pass through the eyeball, has, times without number, been found to be accompanied with a want of power to discrimi-

nate colours, often to a ludicrous extent. The organ is large in great painters, especially great colourists, and gives an arched appearance to the eyebrow; for example, in Rubens, Titian, Rembrandt, Salvator Rosa, Claude Lorraine, and others. A large endowment of the organ gives great delight in flowers and brilliant colouring of all kinds. Nature has profusely provided for the gratification of this faculty, by the exquisite colouring in which her works are dressed. Some metaphysicians consider the pleasure we derive from colours to be the result of the association of ideas. Phrenology has discovered that it is the great gratification of an organ forming part of our constitution. Like that of Ideality, the pleasures we derive from Colour are gratuitous goodness from the Creator's hands.

No. 27.—Locality.

Dr Gall was led to the discovery of this faculty as primitive, by comparing his own difficulties with a companion's facilities, in finding their way through the woods, where they had placed snares for birds, and marked nests, when studying natural history. Every material object must exist in some part of space, and that part of space becomes *places* in virtue of being so occupied. Objects themselves are cognized by Individuality; but their place, the direction where they lie, the way to them, depend on another faculty, a faculty given for that purpose. Without such a power, men and animals must, in situations where objects were numerous and complicated in their positions, as woods, have lost their way. No man could find his own home, no bird its own nest, no mouse its own hole. The use of the faculty will be rendered plain by considering what it is we do when we wish to remember our way through the streets of a large city; we note particular objects, buildings, for example, and observe how they stand in relation to each other, and these relations we can remember, although with a faint recollection of the forms of the objects themselves. The organ is large in those who find their way easily, and vividly remember places in which they have been. It materially aids the traveller, and is supposed to give a love for travelling. The organ was large in Columbus, Cook, Park, Clarke, and other travellers. Geometricians, whose study is the relation of spaces, have the organ large—as was the case with Kepler, Galileo, Tycho Brahe, and Newton. The faculty, when active, prompts the individuals to localise everything, and think of it as in its place.

No. 28.—Number.

The organ of this faculty is placed at the outer extremity of the eyebrows and angle of the eye. It occasions, when large, a fulness or breadth of the temple, and often pushes downwards the external corner of the eye. When it is small, the part is flat and narrow between the eye and the temple. Their Number is a very important relation or condition of things, and requires a distinct perceptive power. Our safety, and even existence, may depend on a clear perception of number. Dr Gall called the faculty '*Le Sens de Nombres*,' 'The Sense of Numbers,' and assigned to it not only arithmetic, but mathematics in general. Dr Spurzheim more correctly limits its functions to arithmetic, algebra, and logarithms; geometry being the exercise, as already shown, of other faculties. Dr Gall first observed the organ in a boy of nine years of age near Vienna, who could multiply and divide, mentally, ten or twelve by three figures, in less time than expert arithmeticians could do with their pencils. Dr Gall adds, 'he had created his own method.' An advocate of Vienna regretted to Dr Gall that his son was so much engrossed with calculating, that he attended to nothing else. Dr Gall compared the heads of these two boys, and found no particular resemblance but in one place—that described above—where they exactly agreed. Dr Gall then went to noted arithmeticians—among them an author of tables of logarithms—and found the same organisation. Many other examples will be found in the phrenological writings.

## PHRENOLOGY.

### No. 29.—Order.

The organ of this faculty is placed in the eyebrow, between Colouring and Number, and is large and prominent, and often pointed like a limpet-shell, in those who are remarkable for love of method, arrangement, and symmetry, and are annoyed by confusion and irregularity. The marked love of order in some persons, and their suffering from disorder, are feelings which no other faculty, or combination of faculties, seems to embrace. Several cases are mentioned in the phrenological books, where it characterised idiots, deficient in almost every other faculty. Mr L——, a late medical gentleman in Edinburgh, was remarkable for the organ and its manifestation. He was pointed in his engagements—for the faculty gives this important habit—neat and careful in his writings, regular in his accounts, precise in his dress, and cleanly in his person. In savages, whose habits are slovenly, filthy, and disgusting, the organ is comparatively small.

### No. 30.—Eventuality.

The organ of this faculty is situated in the very centre of the forehead, and when large, gives to this part of the head a rounded prominence. Individuality has been called the faculty of *nouns*; Eventuality is the faculty of *verbs*. The first perceives mere existence; the other motion, change, event, history. All knowledge must be of one or the other of these two descriptions—either things that *are*, or things that *happen*. In the following examples—the *MAN speaks*, the *WIND blows*, the *DAY dawns*, the nouns cognized by Individuality are printed in capitals; while the verbs, addressed to Eventuality, are in italics. The first is simple existence; the other is action, event, history. Dr Gall distinguished, as the metaphysicians do, *verbal memory*, *local memory*, *real memory*. It is now phrenological doctrine that all the intellectual faculties have their own memory. Form remembers forms; Colour, colours; Size, dimensions; Individuality, objects; and so on.

The most powerful *knowing* minds have a large endowment of both Individuality and Eventuality; and such individuals, even with a medium reflecting organisation, are the clever men in society—the acute men of business—the ready practical lawyers. The organ of Eventuality is generally well developed in children, and their appetite for *stories* is well known. Those, however, in whom Eventuality is moderate, and Individuality large, are prompted less to listen to tales than to 'see things,' as they call the exercise of their more powerful faculty. In after-life, the latter will observe minute existences—will tell how many nails are in a door, and miss one if taken out before their next inspection. The former will make use of incidents when they wish to recall any matter of memory.

### No. 31.—Time.

Whatever be the essence of time as an entity, it is a reality to man, cognizable by a faculty by which he observes its lapse. Some persons are called walking time-pieces; they can tell the hour without looking at a watch; and some even can do so, nearly, when waking in the night. The faculty also marks the minute divisions of duration, and their relations and harmonies, which are called *time* in music, and *rhythm* in versification. The impulse to mark time with the head, hands, feet, and whole body, is too common, too natural, and too strong, not to be the result of a faculty; it is the impulse to dance, almost universal in both savage and civilised man. In some, the impulse, when well-marked time is offered—the better if combined with music, though a well-beat drum may be danced to—is often irresistible. It exists in a diseased state, for we have seen dancing madmen. Dogs, horses, and many other animals give plain indications of possessing the faculty, by their conduct on the return of particular days, occasions, &c.

### No. 32.—Tune.

The organ of this faculty is situated still farther out

than that of Time, giving a roundness to the point where the forehead turns to form the temples. It is large in great musicians; and when small and hollow, there is an utter incapacity to distinguish either melody or harmony. Music may be defined as a species of natural language, depending immediately on either a melodious succession or a harmonious unison of tones—tones, again, being distinguished from simple noises by a peculiarity in the mode of their production. (See *ACOUSTICS*, Vol. I.) The organ of Tune in the human brain appears to have been constituted in relation to these physical facts; and in cases of good endowment, to have a most exact perception of all their niceties, and a power of using them to the production of the species of natural language which we term music. Cases of a low endowment of the musical faculty, or of persons said to want *musical ear*, are of frequent occurrence, though perhaps in many such instances early culture would have brought out some trace of the faculty. The great bulk of mankind possess the organ in a moderate endowment, so as to be capable of enjoying music in some degree. The individual possessing it in high endowment becomes, in all stages of society, a distinguished artist, exercising a peculiar power over his fellow-creatures, so as to rouse, melt, soothe, and gratify them at his pleasure. But the gift, in this active form, is liable to be much modified according as it is accompanied by Ideality, Benevolence, Wit, and other faculties.

### No. 33.—Language.

When the faculties are in activity, either singly or in combination, the impulse in almost all individuals is strong, in many irresistible, to communicate to others the feelings or thoughts produced by them. This may be done by signs, which is natural language, or by words, which constitute conventional. A faculty is given to man and animals which connects feelings with signs and cries; but to man alone is given articulate speech. The comparative facility with which different men clothe their thoughts in words, depends on the size of this organ, which is situated on the super-orbital plate, immediately over the eyeball, and when large, pushes the eye outwards, and sometimes downwards, producing in the latter case a wrinkling or pursing of the lower eyelid. There is no fluent speaker deficient in this organ. There is some doubt of the faculty giving the power of learning languages, and the spirit of languages in philology; the prevailing opinion is, that the faculty of Language has less to do with this power than Individuality, Imitation, and some other faculties. Learning the words and structure of other languages is quite a different thing from applying our own to express our thoughts and feelings.

None of the organs have been better proved to be primitive by diseased manifestation than this. The instances are numerous of persons losing the power of finding words for their thoughts, and recovering it again; and in many of these cases, the brain in the organ when examined after death has been found diseased. Pain in the region often accompanies the loss of appropriate speech, in plague, yellow and typhus fever. But we must refer for further information on this interesting subject, to the works on phrenology, especially to Mr Combe's 'System.'

### Internal Excitement of the Knowing Organs— Spectral Illusions.

The Knowing Organs are for the most part called into activity by *external* objects, such as forms, colours, sounds, individual things, &c.; but internal causes often excite them; and when they are in action, objects will be perceived which have no external existence, and which, nevertheless, the individual will believe to be real. This is the explanation of visions, spectres, and ghosts, and at once explains the firm belief of many that they have appeared to them, and the fact that it never happens that two persons see the same spectres at the same time. We formerly remarked,

when treating of Wonder, that excess or disease in that organ predisposes the patient to believe in the marvellous and supernatural, and probably stimulates the Knowing Organs into action, when spectral illusions are the consequence. A young lady known to Mr Simpson, and mentioned in the phrenological books by the initials of S. L., lived in indescribable horrors for above a year, in consequence of the visits of the spectral forms of persons and other objects, and the perception of bright lights, brilliant colours, music, and other illusions. At the time of these false perceptions, she was strangely affected in the organ of Weight and the sense of Resistance; she lost the power of preserving her balance, and saw perpendiculars and horizontals at other angles. She complained of sharp pain when her visitants appeared to her; and although ignorant of phrenology, and even the situation of the organs, she put her finger and thumb, when asked where she felt the pain, to the organs of Form and Individuality. For several weeks these were the site of her pain exclusively; and then the figures which appeared to her were forms without colour, resembling, as she stated, cobweb. Here plainly was Form active, but Colouring dormant. Some weeks after this her objects became naturally coloured, and the pain extended along the eyebrows, including the organ of Colouring. Embracing, as the progress did, Size, her illusions referable to that organ in morbid activity were singular: she saw objects sometimes gigantic, sometimes dwarfish, and even minute. The pain proceeding onwards along the whole eyebrows, Order and Number became affected, and her visitants came in great numbers and most annoying confusion, so that sometimes they seemed to tumble into her apartment like a cascade, a confused mass of persons, limbs, heads, &c. Her apparitions began at last to speak to her, and her terrors were much aggravated. It was probable that the organs of Language and Tune became affected; for she often heard bands and choruses of music. We may add that she was greatly relieved when the true nature of her spectres was explained to her. In time the affection left her entirely. It is likely that the proximate cause of these morbid manifestations was an undue determination of blood to the region of the head where the Knowing Organs are situated.

GENUS III.—REFLECTIVE FACULTIES.

The Intellectual Faculties already considered give us knowledge of objects, and the qualities and relations of objects, also of the changes they undergo, or events. The two remaining faculties, according to Dr Spurzheim, 'act on all the other sensations and notions'—that is, they judge of the relations of different ideas or classes of ideas produced by the Knowing Faculties. They minister to the direction and gratification of all the other faculties, and constitute what by excellence is called reason—in other words, reflection.

No. 24.—Comparison.

Dr Gall discovered the organ of this faculty in a man of science who reasoned chiefly by means of analogies and comparisons, and rarely by logical deductions. He illustrated everything, and carried his opponent along with him with a flood of resemblances, concluding that the thing disputed must be true, being like so many things that are known to be true. In his head was a fulness in the form of a reversed pyramid, just in the middle of the upper part of the forehead. The faculty perceives analogies and resemblances. Every faculty can compare its own objects. Colouring can compare colours; Weight, weights; Form, forms; Tune, sounds; but Comparison can compare a colour with a note, or a form with a weight, &c. Analogy is a comparison not of things, but of their relations. Dr Spurzheim thought that the faculty perceives difference. Mr Scott dissents from this, and attributes that function to the faculty of Wit. The precise fundamental function of the faculty is yet controverted. Mr Hewett Watson argues ingeniously, and Mr Combe assents to the argument,

that it is the perception of conditions, of the condition in which objects exist. As the organ of analogies, similitudes, and comparison of ideas, it is established.

No. 25.—Causality.

This is the highest and noblest of the intellectual powers, and is the last in the phrenological analysis of the faculties. Dr Spurzheim so named it from believing that it traces the connection between cause and effect, and sees the relation of ideas to each other in respect of necessary consequence. Its organs are situated on each side of Comparison. Some metaphysicians have held that we have no idea of cause, but see only sequence, or one thing following another. It is true that we do see sequence. When, for example, fire is put to gunpowder, Individuality perceives the existence of the powder and of the match; Eventuality sees the motion which unites them, and the change or event which takes place in the explosion; but we have a third idea—namely, that of power, agency, or efficiency, existing in some way in the cause, to produce the effect. Whence do we get this third idea!—from a third or distinct faculty, and that is Causality. With a powerful perception of causation, the individual reasons from cause to effect by logical or necessary consequence. It is the faculty which sees principles and acts upon them, while the other two faculties only try experiments. Resource in difficulties, and sound judgment in life, are the result of powerful Causality. The organ is established.

Adaptation of the External World to the Intellectual Faculties of Man.

We quote the following passage from Mr Combe's 'System' (4th edition, p. 593):—'The human mind and the external world having emanated from the same Creator, ought, when understood, to be found wisely adapted to each other; and this accordingly appears in an eminent degree to be the case. If the reader will direct his attention to any natural or artificial object, and consider, 1st, Its existence; 2d, Its form; 3d, Its size; 4th, Its weight; 5th, Its locality or relation in space to other objects; 6th, The number of its parts; 7th, The order or physical arrangement of its parts; 8th, The changes which it undergoes; 9th, The periods of time which these require we would add here, its sound-producing quality or sonorosity, as quite different from all those enumerated; 10th, The analogies and differences between the individual object under consideration and other objects; 11th, The effect which it produces; and lastly, if he will designate this assemblage of ideas by a name, he will find that he has obtained a tolerably complete notion of the object.' We may add, that the relations between the affective faculties or feelings of man and the moral world are not less harmonious; and demonstrate design in a manner altogether irresistible.

Relation between the Functions and the Structure of the Brain.

An accumulation of facts which amounts to proof as cogent as is to be found in regard to any other physical truth, has connected with the anterior lobes of the brain the Intellectual Faculties, and with the middle and posterior lobes the Feelings. The Intellectual Faculties constitute the will of man, and in obedience to the will are the voluntary motions. But the feelings, when in activity, as is well known, have certain involuntary motions connected with them. Now the spinal cord has two columns—the one, the anterior, observed to produce motion, and therefore called the motory tract; and the other to produce sensation, and therefore called the sensory tract. These two tracts join the brain by what is called the medulla oblongata; and here a most striking distinction takes place. The motory tract alone communicates with the anterior lobes, in which, in the intellectual organs, resides the will. Hence in voluntary motion, as an effect of will, the motory tract obeys the anterior lobe alone; in other words, the anterior lobe of the brain manifests will, and the motory tract executes will. The sensory

tract has no connection with the anterior lobes or intellectual organs.

Again, the *sensory* tract has a fibrous connection with the middle and posterior lobes of the brain, and with the cerebellum, and most appropriately, for these are the organs of the *feelings*. But as the feelings have *involuntary* motions when acting, these are provided for by a fibrous connection between the organs of the feelings and *both* the sensory and motory tracts. Yet, as the motions consequent upon the energy of passion are not voluntary, but instinctive, we should expect a separate motory tract for instinctive motion, with which, and not with the tract of voluntary motion, the organs of the feelings should be connected. This distinction, however, has only been conjectured; it is not yet ascertained. Mr Combe farther adds—'It is certain that mental *emotions* exercise a powerful influence over the organic functions: when the emotions are agreeable, they stimulate these functions to healthy action; and when painful, they depress their energies and produce liability to disease. Reciprocally, when the organic functions, such as digestion, respiration, and secretion, are disordered, an irritable and distressing state of the mental feelings is induced. The intimate relations between the convolutions of the brain devoted to the mental emotions, and the sensory tract of the spinal cord, is in harmony with these facts. The habit of contending with *intellectual* difficulties, if unconnected with feeling, does not injure the organic functions so severely as do strong and powerful emotions; but it weakens the locomotive powers. Sedulous students of abstruse problems acquire a great aversion to locomotion. These facts correspond with the arrangements of structure by which the convolutions of the anterior lobes, devoted to intellect, spring from the motory tract, and are not connected with the sensory tract of the spinal marrow.' We are not aware that anatomical and physiological investigations have unfolded facts more interesting than those now detailed.

#### Natural Language of the Faculties, or Pathognomical and Physiognomical Expression.

What has been stated in the preceding section will prepare the reader for the fact, that, by means of involuntary motions, each organ of feeling produces movements, attitudes, and expressions peculiar to itself. The chief aim of the dramatic actor and pantomimist is to study and represent these movements, attitudes, and expressions; and hence such of them as have studied phrenology, have declared that it affords them the most valuable guidance. Dr Gall's 'Physiology of the Brain,' and Dr Spurzheim's 'Physiognomical System,' enter fully into this curious subject, and have ascertained the laws which determine the natural language of the faculties. It has been laid down as the leading principle, that the instinctive motions are always in the *direction of the organs*. Self-Esteem, for example, throws the head high and slightly backwards, vulgarly called 'turning up the nose' at anything. Firmness gives an erect stiffness to the person. Cautionness throws the head backwards and to the side. Veneration slowly forward; hence the reverence and bow. The involuntary motions extend to the features of the face; hence the dark and harsh expression of Destructiveness, and the smile of Benevolence and Love of Approbation. The countenance tends to take a permanent expression from the prevalence of particular feelings. It is this which renders the physiognomy of phrenology scientifically trustworthy.

#### The Organs arranged in Groups.

It is instructive to find the organs of such of the human faculties as have an affinity to each other, placed contiguously in the brain, and to observe that, by an apparent sympathy, they stimulate each other to activity. 1st, The supposed organs of the Love of Life and Alimentiveness—the essentials of Self-Preservation—lie contiguous in the brain. But man has a carnivorous stomach and teeth, and must destroy animal life

to preserve his own. Destructiveness, accordingly, lies close to the two organs mentioned. He must not only devour the gentler animals, but must not be devoured by the ferocious; hence his Cautionness, Combative-ness, and Secretiveness are all close neighbours of the three organs mentioned, and of each other. The accumulation of surplus above his immediate wants, so important to man's preservation, is prompted by Acquisitiveness; while, without Constructiveness, he would perish for want of shelter and clothing. Thus a cluster of no fewer than *seven* organs forms to man the *self-preservative* group of faculties. 2d, Man is commanded to do more than 'subdue;' he is enjoined, by multiplying his species, to 'replenish the earth.' Behold, then, another group of faculties for this purpose, which may be called the *species-preservative*, or *domestic* group—Amativeness, Philoprogenitiveness, Inhabitiveness, and Adheiveness. 3d, Designed for the society of his fellow-men, man asserts his own rights and legitimate power by Self-Esteem or Self-Love; while he is influenced by the opinion of others to the proper regulation of his conduct by Love of Approbation, or regard to character. Firmness aids Self-Esteem in asserting right. The three organs located close to each other form our *rights and character-preservative* group. 4th, The *moral* group, by excellence, is formed by Conscientiousness, Benevolence, and Veneration *earth-directed*. 5th, The *religious* group is formed by Veneration *heaven-directed*, Wonder, Hope, and Ideality; the last being claimed as a religious faculty by Sir George Mackenzie, as the love of the perfect. 6th, A bountiful Providence has provided a rich fund of recreative pleasure for man in what may be called the *poetical or recreative* group of his faculties—namely, Imitation, Wonder, Ideality, Wit, Tune, and Time, all lying contiguous in the brain. *Lastly*, Turning to the intellectual powers, we have them in one splendid and 'god-like' assemblage in the forehead of man, subdivided into three groups, according to their uses. The lowest range, the *simply-perceptive* group, gives the perception of objects and their qualities. Above it is placed the *relatively-perceptive* group, for perceiving the relations of objects and events; and, above all, the organs of the highest of man's faculties—namely, his reflecting powers, which perceive the relations of ideas, and reason upon them; or the *reflective* group.

#### CONTINUATION OF PHRENOLOGY AS A COMPLETE PHILOSOPHY OF MIND.

The phrenologists have chiefly confined their attention to the organs of the brain, and the various faculties of which these are the instruments. The former writers on mind (Reid, Dugald Stewart, Brown, and others) gave, on the contrary, their chief care to the mental acts called Attention, Perception, Conception, &c. which they considered as faculties. The phrenologist does not overlook the importance of this department of mental philosophy, but differs from the metaphysicians in considering perception, conception, &c. as only *modes* in which the real faculties above described *act*. This distinction is one of great importance.

According to the phrenologists, the faculties are not mere passive feelings; they all tend to action. When duly active, the actions they produce are proper or necessary; in excess or abuse, they are improper, vicious, or criminal. Small moral organs do not produce abuses; but they are unable to prevent the abuse of the animal organs, as the larger tend to do; thus small Benevolence is not cruel, but it does not offer sufficient control to Destructiveness, which then impels to cruelty. Large organs have the greatest, small the least tendency to act—each faculty producing the feeling or idea peculiar to itself. Seeing that all the organs tend to action, the Creator must have intended a legitimate sphere of action for them all. He could never have created either bad or unnecessary faculties.

The PROPENSITIES and SENTIMENTS cannot be called into action by the will. We cannot fear, or pity, or love, or be angry, by willing it. But *internal* causes may sti-

mulate the organs, and then, whether we will or not, their emotions will be felt. Again, these feelings are called into action in spite of the will, by the presentation of their *external* objects—Cautiousness by objects of terror, Love by beauty, and so on. The force of the feelings, whether excited from within or without, will be in proportion to the activity of the temperament. Excessive action of the affective faculties, or the removal of their object, causes pain. Excessive rage is painful to Destructiveness; and the death of an infant pains the Philoprogenitiveness of the mother. Insanity is a frequent result of over-activity of the affective feelings. An affective faculty may be diseased, and yet the intellect sound. The converse is also true. When the organ is small, its feeling cannot be adequately experienced. Hence the frauds of those with small Conscientiousness and large Secretiveness and Acquisitiveness. The will can *indirectly* excite the affective feelings, by setting the intellect to work to find externally, or conceive internally, the proper objects. This accounts for different turns and pursuits. Lastly, the affective faculties do not form ideas, but simply feel; and therefore have no memory, conception, or imagination. They have *Sensation* only; in other words, they feel; hence Sensation belongs to all the faculties which feel, and to the external senses and nervous system in general. Sensation, therefore, is a state or condition, not a faculty, as is held by the metaphysicians.

The KNOWING and REFLECTING FACULTIES, or Intellect, form ideas, perceive relations, and are subject to, or rather constitute, the Will; and minister to the affective faculties. They may be excited by external objects, and by internal causes. When excited by the presentation of external objects, these objects are *perceived*, and this *act* is called PERCEPTION. It is the lowest degree of activity of the intellectual faculties; and those who are deficient in a faculty cannot perceive its object.

CONCEPTION is also a mode of action of the faculties, not a faculty itself. It is the activity of the faculties from internal causes, either willed, or involuntary from natural activity. IMAGINATION is Conception carried to a high pitch of vivacity. Thus Perception is the lowest degree of activity of any of the intellectual faculties, Conception the second, and Imagination the highest.

MEMORY, too, is not a faculty, but a mode of action. It necessarily follows that there can be no such thing as the *general* memory of the metaphysicians, but every faculty must have its own memory. Memory belongs, however, only to the intellectual faculties. It differs from Conception and Imagination in this, that it recollects *real* objects or events which it has actually perceived, and adds the consciousness of time elapsed since they were perceived. The other named modes of action do not require realities or time.

JUDGMENT, in its proper sense, is the perception of adaptation, fitness, and necessary consequence; and is a mode of action of the reflecting powers. In a certain sense, the Knowing Faculties may each be said to possess judgment; as Colouring judges of colours, Form of forms, Tune of music. When, however, we use the word judgment, we mean right reasoning, sound deciding. To this a proper balance of the affective faculties is essential. There can be no sound judgment where any of the feelings are excessive.

CONSCIOUSNESS is the knowledge which the mind has of its own existence and operations, whether these last are affective or intellectual; but as it does not reveal the existence or nature of the powers themselves which think and feel, it was an error in some of the metaphysicians to attempt to discover these powers by merely reflecting on their own consciousness.

ATTENTION is not a faculty, but the application, or *tension*, of any or all of the intellectual faculties.

ASSOCIATION is that succession of ideas in the mind, each seeming to call up that which succeeds; so that, in our waking hours, the mind is never without an idea passing through it. This is a state or condition of the faculties, not a faculty. The metaphysicians have en-

deavoured to discover laws by which, in every mind, this succession is regulated. The uniform associating powers, according to them, are resemblance, contiguity in time and place, and contrast. The phrenological view is, that the predominant faculties in each mind create the associations. Association is a very important principle in mental science. There is a mutual influence of the organs which produces associations; a natural association between certain external objects and certain faculties; and artificial associations may be formed between objects and faculties. For example, long exercise of a particular organ or organs in performing certain acts, renders those acts easy, by the rapid association of the ideas necessary to their performance. Professional skill, in all its varieties, is thus accounted for. Mutual action of the faculties arises from the beautiful arrangement or grouping which we have already described.

PASSION is any faculty in excess. Thus there are as many passions as faculties. Love is the passion of Amativeness in union with Veneration; avarice of Acquisitiveness; rage of Destructiveness.

PLEASURE and PAIN also belong to each faculty, according as it is agreeably or disagreeably affected.

PATIENCE and IMPATIENCE are respectively the results of certain combinations of faculties. Thus Benevolence, Veneration, Hope, Conscientiousness, and Firmness, with moderate Self-Esteem, produce a quiet, meek, resigned, and patient spirit. Apathy is quite different, although often confounded with Patience; it arises from lymphatic temperament or deficient brain. On the other hand, Self-Esteem, Combativeness, and Destructiveness, when larger than Benevolence, Conscientiousness, and Veneration, will be impatient of contradiction. Large Time and Tune give impatience of bad music.

JOY and GRIEF arise from agreeable and disagreeable affections of the faculties by causes of considerable power. Wealth, power, and praise give joy to Acquisitiveness, Self-Esteem, and Love of Approbation; while, on the other hand, the death of a beloved relative affects Adhesiveness with grief.

SYMPATHY, as its name (from the Greek) signifies, is feeling with another, or partaking of his emotions. The laws which regulate the activity of the faculties show the nature of this affection and the circumstances in which it occurs. Two individuals of similar constitution of mind naturally feel alike. This is the sympathy felt in the theatre, listening to eloquence, or witnessing distress and suffering. But there is another kind of sympathy—namely, that which is called up by the activity of a particular feeling in another's mind, manifested by the natural language of the active faculty; thus the haughty air of Self-Esteem instantly calls up a defensive Self-Esteem in those who witness it, if the faculty be powerful in them. On the other hand, Benevolence, with its kind natural language, excites the same feeling in another. Wonder, too, spreads rapidly; and so on.

HABIT may be defined as the power of doing anything well by frequently doing it. But before it can be done at all, there must be the faculty to do it, however awkwardly. Habit, then, is the acquired strength of the faculty by its repeated exercise.

TASTE was held by Mr Stewart to be a faculty, and acquired by habit. Phrenology holds that good taste is the result of a harmonious action of all the faculties. Bad taste is evinced when particular faculties, especially the propensities, break out beyond due limits. Social converse is injured by bad taste in various ways—by displays of vanity, disputatiousness, &c. Bad morality is bad taste; but it is more, it is turpitude. A standard of taste, about which so much has been written, is not a decision of certain objects or qualities of objects as beautiful or perfect to *all* men. This were a vain attempt; but it may be approximated by appealing to the taste of individuals of very favourable and harmonious organisation, which has received the highest possible culture. It cannot fail to strike that good taste, sound judgment, and good morals all require well-balanced faculties.

# LOGIC.

## OBJECTS OF THE SCIENCE.

TRUTH is commonly held to be the great and proper object of human curiosity—the end of all inquiries, the indispensable attribute of everything we call knowledge, and one of the greatest achievements and most glorious possessions of man.

Now all these phrases point to something not always possessed, not obvious, and it may be hard to acquire; and yet there are things correctly called true which are not of this description. It is true that I write, that the walls of a room surround me, that I walked in the streets yesterday; and the personal experience and conscious history of each individual will furnish him or her with an unlimited number of the same kind of truths; but there is neither labour, nor anxiety, nor a very great feeling of exultation accompanying them. It cannot, therefore, be this sort of truth that is so highly extolled.

These facts of personal experience, however, are not the whole of truth or knowledge; they are only a very limited portion of the things known and believed in. We receive many events as true on the experience of others; we can acquire a conviction of the reality of occurrences that have taken place in former ages, or in remote countries. Moreover, in respect to what is yet future, we have often the same certainty as if we actually experienced it. And it is our having to find out, with accuracy and precision, things existing only in the experience of others, and things past, distant, and future, that renders the discovery of truth frequently arduous, as well as worthy of being achieved.

There are thus two distinct kinds of truth and knowledge: the one furnished by personal experience, commonly termed Intuitive, which is of narrow limits, but of the highest possible certainty; the other not obtained from personal experience, and extending over the whole world, and into past and future time. To arrive at a knowledge of this last class of truths, and to acquire certainty regarding them, is an operation of labour and care, and must be gone through in a particular way, which it is possible distinctly to point out.

The class of things not ascertainable by direct experience become known by being connected with known things by a bond that direct experience has ascertained. When we see a flash of lightning, we have a direct experience of a luminous appearance, and we further know that a noise of thunder will follow; that is, we can anticipate and believe in what has not yet been actually perceived. In this case every one is aware that the grounds of the anticipation are, that we have formerly had experience of both events, and that the one has been found to follow the other. And when, on observing that five seconds have elapsed between the flash and the noise, we believe that the place of the thundery agitation is a mile off, it is because the previous experience of the travelling of sound has shown it to be at the rate of one-fifth of a mile per second. So, having observed that flame is usually accompanied with heat, we are ready at any time, when we see a flame, to believe that heat is given forth, though we should not actually feel it. What nature seems to associate together in the world, we come to associate in our minds, and we need only to be directly cognisant of one part of the combination to realise all the rest. This kind of knowledge is called knowledge by Inference; and it will be obvious that it is derived through our previous experience of the occurrence of united events. But as it is not every case of two things happening together which will enable us to feel sure that they will in all future time happen together, we require to have some means of discriminating the conjunctions

that will always occur, from such as may fail at the very time when we trust to them.

If nature furnishes conjunctions of events, or companion circumstances, enabling us, on finding one, to make sure of the presence of a second which may be hidden from the immediate view, it is important that we should know them all; for they will serve to expand our vision, and will give us the means of acting on what concerns us, although not before us. The discovery of all these natural conjunctions, called Laws of Nature, is the discovery of Truth, and the reducing of them to their most naked and simple form, is Science; the conceptions of which approach more closely than any others to the deepest and clearest possible insight into the scheme and mechanism of the universe.

Language, or speech, originally contrived for the communication of meaning, thought, and emotion or feelings, has become a great and indispensable instrument in the discovery of the laws of things, or the natural conjunctions, and united events established in the world. This instrumentality is not absolutely essential to our gaining of knowledge by Inference, any more than it is to knowledge by Intuition: the once whipped dog knows that if it do a certain act another whipping will follow, and this knowledge comes from a pre-established connection of events, which enables the animal to draw the inference. But it is found that we cannot advance far in tracing out the actual conjunctions of nature, nor in deducing conclusions from them in the applications to life, without the help of language or speech, together with certain classes of marks and symbols that are not employed in ordinary conversation, although somewhat of the nature of language. This necessity is owing to the abstruse and hidden character of the greatest and most comprehensive uniformities of nature; for if these lay all on the surface, like the coincidence of sunrise with daylight, our mere notion of the two connected things, derived through one or more of the senses, would be quite enough to put us in possession of the laws.

Logic (derived from the Greek word *logos*, which literally signifies speech or discourse) is the science that treats of the methods for assisting and guiding the human faculties in the discovery of the true natural conjunctions of the world (which are the subject-matter of the various sciences), and in the verification of all alleged conjunctions, and everything that can be a matter of belief or disbelief. It is the science of discovery and proof; it gives the rules for sifting and testing everything we call evidence. By investigating to the bottom the grounds of certainty in all cases of affirmation or denial, it enables us to arrive at what is the truth in instances where the human faculties, unassisted by its methods, would entirely fail.

## NAMES AND ASSERTIONS.

As the truths of which Logic takes cognisance are all mixed up with Language, it is essential at the very outset to give an account of the various classes of names that are involved in affirmations and denials, or that serve to embody the conjunctions found in nature.

The invention of names has been determined by the character of the objects to which they are applied, or at least by the conceptions formed of those objects. This has been illustrated in a preceding paper (No. 52, Vol. II.) on LANGUAGE. The classification of names for our present purpose will be somewhat different from the order of their invention, although coinciding with it in several points. For logical purposes, there are two great classes of names of objects, apart from the verb which serves for affirmation.

## The Different Kinds of Names.

The first class of names includes *individual* and proper names, or the names of single objects—as England, the Nile, Mont Blanc, Niagara, Napoleon; they are the marks or designations of certain individual things or existences, whether natural objects or individual men or animals. They serve merely the purpose of marking out some one thing from among the multitude of things at large, exactly as would be done by pointing to it with the finger, or in any way indicating it to another person. They give no information, and involve no assertion, nor any matter of belief or disbelief; neither do they in general make any comparison between the object and other objects. These names serve the bare purpose of communication, and they are the only names which are of themselves destitute of all logical function.

The second class of names includes *general* names, which are of various sorts, but have all a common character as distinguished from the foregoing. It being found that, notwithstanding the variety presented by nature, there is a great extent of similarities, or many instances of likeness between objects, this likeness striking the human mind has led to the application of a common name to the individuals of each resembling group. Thus supposing *Nile* were the proper name of the first river which came under the notice of a people, and that they afterwards met in with a second river, the similarity of the two objects would strike them at once, and the name *Nile* would be used as the mark of the second as well as of the first. The same process would be applied to a third, and fourth, and so on, till it became the common name of rivers in general. It would now cease to be the exclusive mark of one object, and would denote one of a class of objects possessing common features. To serve the purpose of pointing out a specific individual, some second name would have to be superadded, or some device used, for showing which one of the group was referred to: the first would answer its original purpose of a proper name only by being coppled, or *qualified*, as grammarians term it, by a second name having reference to one individual of the class, and to no other.

At first sight this may seem a cumbersome and clumsy process, since it ends in requiring that each object should have two names instead of one. But, in fact, several very important steps have been gone through, in their nature quite different from the mere affair of giving names for distinguishing individual things from one another. There is, in the first place, a series of discoveries as to a number of natural objects. It has been found out that certain distinct things situated apart from each other in the world, are, nevertheless, to a certain degree like one another. Now the discovery of a likeness in two things is not only an agreeable satisfaction to the human intellect, which would otherwise have to acquire an entirely distinct notion of each, but it shortens and facilitates human labour in many ways. For so far as the likeness holds, the things will serve the same practical purposes, and may be indiscriminately applied according to convenience: it does not require a separate investigation to see what each is good for, but the conclusions from the one can be instantly adopted for the other, thus diminishing the trouble of inquiry; and if we wish to make known their appearance and character to our fellows, it will suffice to call attention to one of them, so that we also lessen the toil of the acquisition of knowledge. Moreover, if we make any new discoveries about one, they are made at once for both, as certainly as if we had gone through the operation for each. If ten objects receiving the common name 'river,' were once completely identified, and if the characters of water, and the origin and movements and termination of a single river were found out, a great deal of knowledge would be gained concerning all the ten without the labour of detailed inspection.

Wherever nature furnishes similarity between diffe-

rent things, it is of the highest advantage to man to detect this similarity; and when once detected, it can be declared and published by the use of a common name without any formal intimation. Thus instead of having ten proper names for the ten rivers above supposed, and of publishing declarations abroad that each has been found to resemble each, which would amount to a most voluminous mass of statements, all that is requisite in common discourse is to apply the one name to them all. The fact of similarity is thus insinuated and conveyed by every instance of the use of the common name. When a great discovery of identification has been made, like Franklin's discovery of the resemblance of thunder and lightning to the phenomena of a common electrical machine, it is published to the world most effectually by henceforth using the same name for both things; as when the newspaper accounts of thunder-storms use the phrases 'electricity' and 'electric' as part of the description. General names have thus a high and important function in respect to our knowledge of the world, and it is essential that they should be properly and guardedly used. Since they assert identities of objects, they may mislead us by a mere pretended identity; in which case our whole procedure respecting the objects would be perverted. It is therefore one part of the business of Logic to state the precautions necessary for the use of common or general names.

To understand fully the different species of general names, we must consider a process that takes place subsequent to the operations of identifying different objects and imposing a common name, and to the general use of this name to indicate their similarity, as well as to serve for their designating mark. This process is what is termed 'abstraction,' and is often a process of nice and delicate analysis, and of subtle invention. When we have found that several objects make nearly the same impression on our minds, without its being altogether the same, we desire to divide our conception of each into two parts—the one being the coinciding portion, and the other the differing portion—and to give a name or description of each, so as to keep them apart in our own minds and in the minds of others. This splitting up of a complex conception, with the view of fixing and describing it, is sometimes very easy, and sometimes one of the most difficult operations of the human understanding. If we see two knives exactly the same in the blade, but differing in the handle, we can easily state and describe both the agreement and the difference. A mechanical division of each into two parts, and the giving of one name to the common blade, and two distinct names to the differing handles, and pointing out what we mean by each, would be sufficient. We should thus be able to state why we used one name for both, and also why the common name would not always be enough to point out each. But if we take the general group named 'houses,' which have common properties as well as a common name, we cannot divide the conception so easily. The thing common to all houses could not be cut off from one of them, leaving exactly the points of its distinction from all the rest; neither can we point to any portion of the object as the thing common to all. We must bring in extraneous matter into this case, and state the common attributes of houses by a reference to other objects besides themselves; we must say, what is common to a house is its affording shelter, accommodation, and protection to human beings, or their valuables. But this is not an effort of mere analysis: it involves a complicated reference and a complicated description; it is, nevertheless, the only way of pointing out to ourselves, or to others, what that common thing is which enables a common term to be used for this class of objects, and a constant assertion of similarity to be made through that common term. And when once we know the agreeing part of the objects, we can find the non-agreeing part by what remains; or we can see that houses differ in size, form, colour, material, &c.; so that when one has to be

specified from all the rest, if it has not a proper name (such as St Paul's, St Peter's), language must be found to describe exactly what are the features wherein it differs from other houses, or from houses in general. The common attribute, once distinguished and represented to the mind, is called the *abstract idea* of the objects, because it is supposed to be withdrawn or cut away from the total mass as existing in nature. In the case of two knives of the kind we supposed, the abstract part is a material portion of the thing; in the case of the house, it is not a material portion, but a complicated description of relations with other objects. In thus going through the wide range of classes, or identified groups, we will find the greatest variety in the nature of the common parts of each class, and in the mode that must be had recourse to in order to state it. We shall here present a few examples of these varieties:—

The case of mechanical division of the agreeing from the differing part is of frequent occurrence, but requires no farther exemplification. A case somewhat more complex is when different objects contain a common ingredient mixed up or diffused through them—as in the case of wet bodies (which agree in containing water), salt bodies, sugary substances, and the like. The process of abstraction in this case would consist in separating the common ingredient, or determining what it is, and giving it a name; or if it has a name already, then the common designation of the class of objects would be derived from this name. Thus ores containing iron as their chief ingredient, are called iron ores; so we speak of siliceous minerals, clayey soils, &c.

A more subtle case of analytical abstraction is presented by objects which agree in things that cannot exist apart from the objects themselves, and whose designations therefore must not be such as to suppose a separate existence. Thus colour is generally such a common attribute; likewise form, hardness or softness, solidity or fluidity, taste, smell, are of the same character. No substance can exist having one of these effects alone in the absence of all other effects. Matter is so constituted as commonly to act upon the human organs in two or three ways at once; and we can discriminate the effects in our minds, although we cannot separate the properties causing them into different individual substances. Thus an orange may act upon the touch, on the sense of form, on the sight, on the taste, and on the smell, and we may have conceptions of each effect in some measure apart from all the other effects. We may smell it without receiving any other impression; the only impressions apparently inseparable are the sight and the form. But although these are not easily separated in the action upon the sense, they are felt to be a joint, although co-existing effect; and the intellect can effect a separation by giving a name and description to each, according to the feeling of the part of the impression that each produces. Thus we recognise an identity in all objects having the round form, whatever the colour may be; and although this form is always of some colour, we separate the form from the colour intellectually in two ways—the one, by giving a name that shall express the impression of form to the exclusion of an impression of colour; the other, by making a round form with a thin outline, or with the smallest possible amount of coloured or material surface to indicate that we wish to confine our consideration to the form by itself. Both methods are adopted in the study of forms in geometry: names are given to them apart from substance and colour; and fine outlines are made so as to exclude as much as possible these other impressions from the view of the mind. In the more complex case, therefore, of inseparable material attributes, it is still possible to recognise identity in the midst of differences; to have a distinct conception of the agreeing portion of the objects; and to give a name, a description, or a diagram to the common part which may be adopted as the general name of the group so agreeing. Thus we have things bitter, sweet, hard, rough, red, white, round, square,

&c. Bodies acting on the sense of hearing, in addition to the other senses, are conceived apart and designated apart from their audible impression without any difficulty. There are also objects that agree not in any impression on the senses, but in some deeper impression on the more inward emotions—as things grand, terrible, beautiful, &c.—which effects can be separated by the intellect from the other effects, although the causes of them are inseparably joined with other causes or properties. In all such cases the formation of what is called an abstract conception may be made clear and intelligible; and the subsequent processes of naming and describing this conception, so as to make it an object of communication and common understanding, will be intelligible also; as in like manner the application of this common designation as a name of the whole group of objects that are found to produce on our minds the agreeing impression.

A still higher and very numerous class of abstractions are those exemplified in the previously-quoted case of houses, where the objects do not produce an identical impression except in company with other related objects. The process, however, is still essentially the same. The coinciding part of the various individuals makes an impression of its own, which may or may not be separable in the immediate sense from other things where the individuals differ, but which is separable by the devices known to the intellect—namely, verbal description, or pictorial or other representation; which description or representation is the abstract term and common handle of the conception, enabling it to be considered by the mind, and made known from one person to another; it will also serve as the general name of the things possessing the common attribute. Most of the abstractions of science are of this complex kind—as, for example, force, affinity, pressure, magnetism, analysis, vitality, virtue, imagination, government, security, civilization, &c. In all these a complicated group of material objects has to be involved; and sometimes one class of conceptions, direct from the material world, has to be wrought up with another like class, and these again refined upon until the resulting conception is many removes from the actual things existing in nature which were at the base of the whole. For instance, the mathematical idea of integration, and the chemical idea of double decomposition, are the results of a series of conceptions elaborated out of one another, although having their first commencement in the impressions of the objects of the material world. In them the purely intellectual operations of naming, describing, and combining greatly predominate over the operations of comparing sensible impressions.

An important distinction among general names is brought out in the use of the phrases generic and specific names. In natural-history classifications these are constantly employed. Certain objects are called *species* in reference to certain others called *genera*, and the one is usually said to be included into the other. Thus Man is a species, and the class of two-handed animals is a genus, including the species Man along with others. Iron is a species, the metals are a genus. A species must be a class of objects agreeing in all the properties common to the genus, and in some other properties not belonging to the whole genus. Thus iron has all the characters of the class of metals, and certain others not belonging to the class. But the class 'metals' itself might be the species to a more comprehensive genus—'simple bodies;' and this might be a species in a still more comprehensive genus—'material bodies;' just as 'two-handed' might be a species compared with animal, and animal a species compared with living bodies, which include both vegetables and animals; so that genus and species are correlative terms, being both connotative general names; but the one connoting fewer attributes than the other, is on that account less exclusive or more comprehensive.

But there is one particular and important application of the term 'species,' founded upon the existence of a marked and distinguishable class of natural ob-

jects, which we must here point out. There are certain kinds of objects that agree with one another, and differ from all other things in a great and unknown number of attributes; so that their agreement with one another is very intimate, and their distinction from all other things very wide. Thus if we take human beings, we find that they have an exceedingly large and complex agreement, or they possess more features in common than we can enumerate, or than we may ever be able, after all our study of the human subject, to reckon up; for to know them all would be to attain the perfect knowledge of man. It is the same with many classes of animals. If we take the dog, we find that there is an almost inexhaustible fund of common features which mark the dog as a kind apart from all other animals and things. So iron, silver, phosphorus, are of this description: the specimens of any one agree with one another in all the properties discovered and undiscovered that attach to that one; the entire discovery of all these properties being the perfect knowledge of the species. Such objects are called 'lowest species,' or 'lowest kinds,' because they cannot be subdivided into others, having the same totality of differences from one another. Thus if we divide man into white, red, tawny, and black races, these cannot be called species in consequence of these distinctions alone: if all the difference between one race and another can be expressed in one single attribute, such as colour, or in two or three definite attributes, then these races are not different in kind, they are not specifically, or *in toto* distinguished; the subdivided classes are called varieties, and not kinds. But if it were discovered that an indefinite and unknown number of properties distinguished a Negro from a European, as in the case of a man and a monkey, or a dog and a horse, European and Negro would be different kinds. The classes that are not separate kinds may be exemplified by solids, liquids, and gases, of the same substance; for these differ only by a limited and assignable difference, all traceable to the one agency of heat. So houses, lands, rivers, are true classes, but they are not true kinds; for the extent of their agreement with one another, and of their difference from other things, is limited and assignable; very unlike the differences between iron and gold, which affect all the senses, and which ramify and show themselves in a boundless number of ways.

All the names of kinds are nouns; and although adjectives and abstract terms are formed from them, it is always a limited and imperfect derivation. Thus the adjective 'manly,' and the abstract noun 'manliness,' are very far from expressing all that is common to man; they only point out some one property which conspicuously attracts attention for some reason or another. But the names of classes that are not kinds readily take on the adjective and abstract form—as 'liquid,' 'liquidity;' 'circle,' 'circular,' 'circularity.' These derivations are perfectly strict and proper; and it is only such names as are formed from classes, not kinds, or limited and ascertained in their common features, that can properly yield adjectives and abstract nouns with a strictly logical application.

#### Nameable Things.

It is of importance, as a preliminary to explaining the nature of affirmations or assertions, to have a general view of the things presented to us for receiving names, and for becoming the subjects of such affirmations or assertions; in other words, it is convenient to possess a comprehensive classification of the whole of the things that can become part and parcel of the thoughts, conceptions, or knowledges of men. Mr John Stuart Mill, in his great work on Logic, has devised a classification of the universe of knowable and nameable existences as follows:—

1st, Feelings, or states of consciousness, or everything which the mind is said to be aware of, or which produces an influence upon it. These include all sensations, thoughts, emotions, activities, volitions, and whatever is said to be felt or entertained by the human mind.

This is the most immediately ascertained class of the universe of things coming under our cognisance.

2d, The minds themselves which experience the feelings. We require to distinguish the mind from its susceptibilities, and to define it as the thing in which all these reside.

3d, The bodies or external objects that are the causes of those feelings, or states, or consciousness, and all the special powers or distinguishable properties of these bodies. We have already explained that it has pleased Nature to provide substances which have a manifold effect upon the human susceptibilities, leading to distinct conceptions, and the imposition of separate names for the various powers or properties thus made known. The world of outward objects—these objects being taken as wholes, and also as possessing each a numerous assemblage of powers, which must be named and described, as well as the total masses—makes one large class of our nameable and knowable things, and as such must be recognised in Logic. We can only be aware of these by their action on our minds; and hence it is necessary to class them subsequently to the states of consciousness or feelings which make them known, and which alone are properly present to the mind. The external universe does not require for our present purpose to be more minutely classified; the chief point regarding it being the point now stated as to the complex power of its individual objects upon the mind, upon which the whole of the abstractive process is founded.

4th, The Successions and Co-existences, the Likenesses and Unlikenesses, between feelings or states of consciousness, and between the outward objects that produce them. In addition to the individual feelings of the mind, and the individual objects of the world, we are led to take notice of their positions, movements, and similarities, or want of similarity. If thought and nature were dead and still, there would be nothing to mark but position; but as both are incessantly moving and changing, we must take cognisance of the movements, and see how one thing follows another. If no two things were ever alike, perception of Likeness would be impossible; but as the world has been constituted on the principle of repeating the same objects in innumerable circumstances, the examples of this must force themselves on our attention, and we must signify, by appropriate names or descriptions, that such likenesses occur, so far as we descry them. Our conceptions are at the mercy of the outward universe, and ought to follow it as closely as possible; hence our processes of naming, with the view of communicating our knowledge, ought to correspond to the same common source of sensation and thought. We must therefore, in addition to feelings, objects, and their properties, possess a means of describing the co-existence of these, their successions, their likeness, and unlikenesses; and beyond these there is nothing that we can take a hold of. We exhaust all that passes in our minds, and all that we suppose to pass in nature, in the comprehensive grouping of Feelings, Minds, External Causes of Feeling, and the Co-Existences, and Successions, Likenesses, and Unlikenesses of these Feelings, and their external causes. The entire action of the universe on the mind of man presents nothing that is not included in these four heads.

#### Nature of Assertions or Propositions.

In our exposition of names, we made no reference to matters of belief or disbelief. We spoke of objects and of their properties, conjunct and single, and of the conceptions formed of these, and of the names and descriptions given of those conceptions; but a mere notion or conception is not a matter of belief. We must now, however, proceed to state the nature of assertions, affirmations, or propositions, which all mean things to be believed or disbelieved, and therefore to be proved or disproved. A matter of belief means something we can act upon; something that will enable us to do one thing for the sake of attaining some other thing. When we say 'bread is nourishing,' we do more than announce

an object, 'bread,' and a property, 'nourishing:' we tie these two things together with a bond of union which rouses the activity of the human mind, and causes it to set to work in some given course. Assertions are not idle notions, but things of power and might; they are the intellectual machinery that rules the greater part of human life. When a man feels the want of nourishment, and is reminded of the assertion that 'bread is nourishing,' he applies his active energies to procure the bread, in the full assurance that he will thereby have something more than meets his eye in a loaf: that he will have his bodily strength renewed, and his appetite gratified. Belief is the state preliminary to action, or the state disposing to action when some given emergency arises; and assertions or propositions are what call forth this faith or belief.

An assertion requires, in the first place, that there should be two things mentioned: it is not possible so to mention a single object as that it shall be a matter of belief or disbelief. Thus 'fire burns,' 'gold is yellow,' 'bread is nourishing,' 'the sun is the centre of the planetary motions,' each contains at least two things or notions coupled together. Fire is one thing, burning is a different thing, if there be any meaning or anything to believe in the assertion. But the mention of two things is not enough: the two names of 'gold,' 'yellow colour,' do not make an assertion of themselves; the asserting power is conferred by the verb 'is;' and we shall find that every assertion requires a verb, or that the verb is the part of speech which completes the force of an assertion, or has the power of causing belief or disbelief in the human mind. The question, then, arises—what is the import of those verbs which are the bonds of union between the things coupled together in assertions?

As assertions can relate only to the actual facts and appearances of the world, they must refer to some of the great classes of things above enumerated, as constituting the entire universe of the knowable. Accordingly, Mr Mill has shown that all possible assertions may be reduced to five general heads, determined by the fourth class of nameable things, or the class comprehending Successions, Co-Existences, Likenesses, and Unlikenesses. If we add to these four things the idea of mere Existence, we shall possess a summary of everything that can ever come to be asserted in any affirmation or proposition.

We may, however, premise, before illustrating this statement of the meanings of assertions, that propositions may be either affirmative or negative: they may either propose something for belief, or as a ground of confidence and action; or they may propose something for disbelief, forbidding us to accept such thing as a ground of action. This is the only real and permanent distinction among propositions as to the form of their making their assertion. Other divisions, as into simple and complex, and into categorical or unqualified, and hypothetical or conditional, are not fundamental divisions. Each complex proposition may be reduced to simple propositions; and the conditional or qualified assertions may also be put in a form resembling the categorical or unqualified.

It may be said, then, of assertions or propositions, that they affirm or deny some one or other of these five things—Existence, Co-Existence, Succession, Causation (a peculiar and important kind of Succession), or Resemblance. No proposition can be enunciated, no piece of knowledge or information conveyed, nothing believed or disbelieved, nothing presented as a guide to human action, that does not assert or deny of some thing or things one of these five attributes.

In the case of Existence, a single object or thing is sufficient material for an assertion—as when we say, 'the sun exists,' 'God is.' But in all the others, it is obvious that there must be at least two things; for the very nature of the attributes of co-existence, succession, and likeness, is to imply plurality—to co-exist, to succeed one another, or to resemble one another.

Propositions of Co-Existence are such as—'London

is situated on the Thames;' 'the battle of Hastings was fought in 1066;' 'the sun is in the sign Aries.' And the assertions of the properties of things belong to the same class—as when we say 'silver is precious,' 'tigers are ferocious,' 'man walks upright.' We have remarked that nature produces objects that have a manifold action on the human susceptibilities; each separate action being commonly called one of the properties of the entire object. Now when we assert that certain properties of a thing accompany certain others, we make affirmations of co-existence. 'Gold does not rust,' is a proposition which may be interpreted to mean that a certain substance recognised by us as yellow, heavy, and of high marketable value (the popular and obvious characteristics of gold), has also the property of not rusting, like iron or lead.

Propositions of Succession will readily occur to any one. 'Night follows day;' 'Queen Victoria followed King William IV.:' and all the affirmations of historical narration are propositions of this kind. The distinction between geography and history is a distinction between the contemporaneous and the successive: the propositions of geography express co-existence and order in place; those in history, succession and order in time.

The particular case of succession entitled Causation, is one very important in respect to the order of the world, and to our knowledge of that order; and although the idea of a cause and effect is familiar and intelligible to most people, it belongs to Logic to clear it up, and to represent it with the utmost possible precision, so that there may not be any doubt hanging over it in the most obscure and perplexed instances which can possibly occur. We shall have to take this up at an after stage; and at present we need only remind the reader, that the succession of cause and effect implies a fixed and invariable bond of connection, such as is never to be interrupted at any time, or under any circumstances; we commonly recognise a sort of unflinching power in the cause to bring on the effect, which we may confide in to the very uttermost.

We have compared geography with history, as exhibiting generally the contrast of the contemporaneous with the successive; and we may likewise compare natural history, which exhibits the properties conjoined in the individual objects of nature, with the sciences of physics, chemistry, &c. which are sciences of causation, in order to contrast the contemporaneous things bound together by a natural and indissoluble bond, with the successive things bound together with the same indissoluble connection. The conjunctions of geography (such as 'the Atlantic divides Europe from America,' 'Africa is the country of the Negroes') are in great part loose and casual, and so are many of the successions of history; but the conjunctions described in natural history are firm and unalterable, and belong to the deep and fundamental collocations of creation; and in like manner the successions of cause and effect are nature's unalterable successions. The contrast between anatomy and physiology is a limited example of the same distinction: the delineations of anatomy refer to co-existing objects, bound together by nature's links for connecting the properties of kinds; the laws of physiology are laws of Cause and Effect. 'The diamond is composed of carbon,' is a proposition of fixed natural conjunction; 'heat liquifies solids,' is a proposition of fixed natural succession or causation.

The only remaining kind of propositions are the assertions of Likeness or Resemblance, which are totally distinct from assertions of contiguity either in place or in time; but they have the same natural basis as these—that is, nature, besides presenting contiguities, both loose and fixed, presents a copious store of similarities among the objects that she reveals to our knowledge. These similarities are usually considered to be of all degrees; but, strictly speaking, this is not the case. The idea of unequal similarity arises from the fact already alluded to—that a number of natural objects are often found agreeing in some of their properties, and not in others; and, speaking of the entire objects,

we say that they have only an imperfect or partial similarity. The most perfect similarity is what is called Identity—that is, taking the same object at different times, no change having happened to it meanwhile, we call the two appearances identically the same. Next to this is the similarity of different specimens of the same substance or kind.

The one science wholly founded on propositions of similarity is mathematics.

The procedure of discovering and verifying these different classes of affirmations is different for each; and it belongs to Logic to prescribe methods for them all. It requires one style of investigation and of proof to establish propositions of causation or of fixed succession, and another set of operations to determine the propositions of fixed co-existence; while the propositions of likeness are found in a way differing from either. Each of these methods will be alluded to when we come to speak of Induction.

#### Definitions.

By far the most important distinction in the whole science of Logic, or in what constitutes the essence of human knowledge, is the distinction between propositions and definitions; or between affirmations and conceptions, verbs and nouns. A definition we have already shown to be the accurate expression and description of some abstract quality of which we have formed a conception, after a comparison of the different objects agreeing in the possession of such a quality. We stated that the final step in the process of abstraction was the making of some accurate description of the property abstracted, whether by words, by diagrams, by models, or by some specimen that contains the quality as little mixed with others as possible. In short, the great end of a definition is to fix by some intellectual machinery the character of an abstract conception, notion, or idea. But we have just found that a proposition couples together two ideas, and cannot possibly contain less. A definition communicates a notion or idea to the mind, it gives us one conception more than we had previously, or communicates a perfect representation where perhaps we had only a vague idea before; but it gives nothing that can be called knowledge, nothing to be affirmed, or denied, or acted on; in respect of these matters, it is only one of the things that may enter into a proposition. Two abstract ideas duly connected may make a proposition; one idea never can. For the purposes of discovery and of the investigation of nature, both definitions and propositions have to be sought; but both must not be sought as if they were the same thing. A definition and a proposition usually agree in this—that they are both the results of generalising from a number of instances; but the generalisation of an idea, and the generalisation of a law or a conjunction of ideas, should never be confounded. The imperfect recognition of this vital distinction is a source of much error and perplexity, both in matters of science and in questions of truth and falsehood apart from science. In seeking a definition of an abstract property, we ought to muster the individual objects in which it occurs; compare them together in order to obtain a clear picture of their common property; and finally, invent some description, designation, or representation which will so express and fix it, that other people may be able to conceive the property with the same rigid accuracy as the person who went through the labour of making the comparison.

All definitions must refer to something which does not itself require to be defined, or which is plainly and clearly known to all men, and requires only to be named that it may be truly and justly conceived. Thus when the abstract property of roundness, or the circular form, is defined in geometry, reference is made to a central point and a straight line running out from, and revolving round it in the same plane. Now the idea of a point, a straight line, and a plane, although they themselves are formally attempted to be defined in geometry, are examples of things so clearly per-

ceived in general, that mankind could not be mistaken in any conception made up of them.

For the sake of accurate reasoning, every general attribute whatsoever should be accurately defined. Hence a book of science must be a storehouse of definitions as well as of propositions, although these last alone constitute information or truth. It is common for parties in disputes to make each other define their terms—that is, to describe in some unmistakeable way the attributes intended to be expressed by the general or abstract words made use of. But it requires a high degree of advancement in any science to furnish perfect definitions of all the properties that it is concerned with. The generalisation and the verification of a definition is as much a process of discovery, and stands as much in need of human capacity and labour, as the generalisation and verification of a law. Hence it is only in subjects which have attained a high scientific development that accurate definitions are found. In the abstruse sciences of mind and society, good definitions are not in all cases attained, any more than good propositions. Thus the perfect definitions of 'will,' 'virtue,' 'beauty,' 'poetry,' 'genius,' 'civilisation,' can hardly be said to be as yet completely attained.

As the things which go together by the ordination of nature, or the conjunctions which, when expressed in language, form propositions, are more frequently made up of separate attributes than of complete objects, the importance of definitions as preparatory to propositions must be evident. Thus when we say, 'electrical excitement is always polar, or consists of two opposite excitements,' we state a proposition asserting the conjunction of two very abstract attributes; and the proposition could not be discovered, nor proved, far less affirmed and acted on, until a general idea was formed of electrical excitement, and likewise of polarity, by the process of generalising and defining. 'The magnet has opposite poles,' is an instance of the same: magnetism does not reside invariably in one concrete substance; it is a highly abstract property, sometimes found in one substance, and sometimes in another.

#### RATIOCIATION, OR ARGUMENTATIVE INFERENCE.

Having ascertained the import of affirmations or propositions, we come next to consider the nature of *proof*, or of the process that is gone through when an affirmation is said to be proved. In most cases of proof, one or more affirmations are put forward which are already believed or admitted to be true; and some new affirmation is derived from these, or said to be established as following or flowing from them. 'John has come to town: I saw him an hour ago,' is an assertion made and proved by the help of another assertion. 'You will get better by taking rest: I myself got round by that means,' is another example. It is a part of Logic to ascertain the nature of the connection between one proposition and another, that will justify the belief of the one on the faith of the other.

It has been shown by logicians, that when one assertion is proved by the help of others, there are always at least two previous assertions necessary to make the proof. These two assertions have been technically called *premises*, and the one that they prove is called the *conclusion*. In ordinary cases, one of the premises is a general proposition of any of the five kinds—namely, Existence, Co-Existence, Succession, Causation, or Resemblance; and the other premise is a proposition of resemblance. For example, 'the planets are round; Neptune is a planet, therefore Neptune is round.' Here the first assertion is a general proposition of co-existence, or an affirmation that certain bodies that circle round the sun have the attribute of roundness; or that the attribute of describing circles round the sun coincides with the attribute of roundness of form. The second assertion is, that Neptune is one of the planets, or is a body circling about the sun; or that he resembles the bodies called planets, or that his peculiarity of movement is like their peculiarity. The conclusion or inference is, that Neptune is a round body.

It is obvious that if we have obtained proof, or acquired certainty in respect to the two assertions or premises in this case, there can be no doubt about the third; for when it is shown that Neptune is entitled to be called a planet, that body is included in the sweep of the general proposition that all planets are round. There are, therefore, always two things necessary in a step of argumentative proof: in the *first* place, a general proposition has to be established; and in the *second* place, an identification has to be made out between the subject of the general proposition and the subject of the affirmation that is to be proved. This last point is merely the practical application of a general affirmation to a special instance. The other step—the establishment of a general proposition—is the business of a scientific inquiry, and has to be done once for all by the proper machinery.

The case we have now given of a step of deductive inference is an example of what is called a *syllogism*; and it used to be reckoned the chief business of Logic to lay down rules for the correct performance of this deductive inference, or for the shaping of valid syllogisms, the two assertions or premises being supposed to be proved, or to have been previously ascertained to be true.\* But it is now considered that the most serious and difficult part of the process of arriving at true conclusions, is the establishment of the general propositions which include them. By what process do we come to be sure that all the planets are round—that all men are mortal—that all matter gravitates—that all chemical combinations take place in fixed proportions? We must not merely provide for the correct application of propositions which have once been proved, we must also provide for the proof of these fundamental propositions themselves.

INDUCTION.

Induction is the term applied to the process of forming and establishing general propositions, principles, laws, truths, or affirmations—that is, propositions which are applicable not to one case only, but to all cases that have a certain definable peculiarity; as when we say, 'gold is heavy,' in which case we affirm that all substances having a certain colour and lustre are also of great specific gravity.

The first question that occurs to us respecting these general affirmations is—how and when are we entitled to make such very broad assertions? We have no means of ascertaining the laws and coincidences established in nature, except the observation of what the world presents to us. If we see that the qualities of yellowness and a peculiar lustre are combined with heaviness, we are entitled to assert the fact in as many instances as we have verified by examination. In like manner, if we see that water quenches fire, we may assert that it is so in the cases noticed. But there remains the grand difficulty—namely, why are we entitled to say that these coincidences and successions take place not only in the cases where they have been observed, but also in the cases where they have not been observed, and in all cases whatever? For this is implied in every general proposition.

This question is answered by the fact, that nature is uniform. There is a certain class of coincidences or co-existences which we have already alluded to as tight co-existences, which are everlasting and unvaried, and need only one observation to tell how they will be in every variety of times and places; and there is a certain class of successions called Successions of Cause and Effect, that are of the like unchanging kind, being the same yesterday, to-day, and for ever. Hence, in these cases, one observation is as good as a million; we are entitled to express or affirm infinitely more than we actually find. It is from nature's repeating herself in endless ways that human labour is shortened to such an extraordinary degree, that a few years of the short

life of man suffices for obtaining a very extensive mastery of the vast and varied appearances of the world.

We have asserted that nature is uniform in her coincidences of the properties of kinds, and in her successions of cause and effect. But, it may be asked, what proof have we to offer in support of this assertion, which is of such magnitude and importance as to be the foundation of our proof of all other assertions, and the means of enabling us to convert a single case of observation into an infinite belief?

There is no other proof to be offered for the uniformity of nature than the unbroken experience of the human race. Every age has found it so; and in the more recent times of human history, it has been tested in every possible variety of ways, and no valid exception has ever been recorded. There was a time when men might entertain doubts on the matter, or when the confirmation was but limited, and the apparent exceptions irreconcilable with the doctrine. But this time has now gone by, and the principle has come to be established upon a basis that seems impossible to be shaken; and all the future generations of men will rest upon it with unswerving confidence. Some have derived the proof of the principle from an instinct in human nature, which leads us to expect this uniformity; but this is to rest upon a most perilous assumption—namely, that the native instincts of men can correctly anticipate the laws of the outer world—an assumption indeed that is far from true. The very same instinct which leads us to expect uniformity in nature, also prompts us to believe that all other men are like ourselves; that our experience is the experience of the whole world; and that what is at variance with it must be false. It is the instinct that urges the inhabitants of a tropical climate to denounce as liars and impostors the people who assert that water can become solid like glass. Such an instinct is utterly untrustworthy, until corrected by the observation of the actual world; but it is extremely valuable as an impulse advancing in the same general direction with the results of our experience.

The laws of causation, or the successions of events established by nature, and invariably adhered to, make the first and foremost subject of inductive investigation. In this case the great problem given for mankind to solve is—to find the effects of all causes, and the causes of all effects.

The general maxim of the uniformity of nature does not always apply to the outward appearances of things. A south wind brings rain one day and drought another; and in many other cases the law of strict succession fails to hold good. The reason of this is discovered by a very little examination: the superficial phenomena of the world, the things that prominently arrest our attention, are not single trains of causation, but mixtures of many different trains; and the law of uniformity does not necessarily hold good, except in the simple and indivisible sequences of phenomena and events. No doubt if a certain number of causes acting together produce a certain amount of effects, the very same combination will always produce like effects; but it is not easy to make sure that two given combinations are really the same. In order to do so, we must first become acquainted with the simple causes one by one. Induction, therefore, in such a state of things, is essentially a process of analysis, or the separation of the complex threads of causation, with the view to determine the simple threads; and when we have once possessed ourselves of all these, we will be prepared to calculate the effects of any combinations of them. Nature rarely presents us with a cause and its effect standing alone. The usual case is to have a multitude of effects flowing from a multitude of causes. It requires, therefore, the whole analytic force of the mind to be devoted to their reduction to single couples of cause and effect. This frequently involves a very difficult operation of the abstractive faculty.

The great object of inductive inquiry being to ascertain among a multitude of connected things, which of them stand to each other in the relation of cause and

\* For a brief account of the Scholastic or Syllogistic Logic, see 'Chambers's Journal,' No. 219, New Series.

effect, we have now to consider the methods of observation and experiment suited to this determination. By 'experiment' is meant the process of altering the arrangements presented by nature, and shaping new arrangements of our own to assist us in ascertaining the simple sequences of cause and effect. Thus if nature presented to our observation a confused and complicated train, and if we contrive to remove a great many of the circumstances, so as to reduce the train to a more simple sequence, we are said to proceed by experiment. If we find or observe a certain locality is exceedingly favourable to health; and if, in our wish to ascertain which of all the peculiarities of the place is the cause of the wholesomeness, we endeavour to put ourselves into situations where each circumstance is excluded in turn, we are said to proceed experimentally. Mr Mill has laid down the different ways of arriving at cause and effect by this experimental procedure, under the title of the 'Four Experimental Methods'; which he names the Methods of Agreement, of Difference, of Residues, and of Concomitant Variations.

'The simplest and most obvious modes of singling out from the circumstances which precede or follow a phenomenon those with which it is really connected as an invariable law, are two in number: one is, by comparing together different instances in which the phenomenon occurs; the other is, by comparing instances in which the phenomenon does occur with instances in other respects similar, in which it does not. These two methods may respectively be denominated the Method of Agreement, and the Method of Difference.

In illustrating these methods, it will be necessary to bear in mind the twofold character of inquiries into the laws of phenomena; which may be either inquiries into the cause of a given effect, or into the effects and properties of a given cause.

For example, let the antecedent be the contact of an alkaline substance and an oil. This combination being tried under several varieties of circumstance resembling each other in nothing else, the results agree in the production of a greasy and detergent or saponaceous substance. It is therefore concluded that the combination of an oil and an alkali causes the production of soap.'

Mr Mill states the method of Agreement in a formal canon as follows:—*If two or more instances of the phenomenon under investigation have only one circumstance in common, the circumstance in which alone all the instances agree is the cause (or effect) of the given phenomenon.*

By the method of difference, is meant the process of comparing two sets of circumstances—one containing the effect, and the other not; and where between the two we can see no difference except in one other particular. 'When a man is shot through the heart, it is by this method we know that it was the gunshot that killed him; for he was in the fullness of life immediately before, all circumstances being the same, except the wound.' This method is expressed as follows:—*If an instance in which the phenomenon under investigation occurs, and an instance in which it does not occur, have every circumstance except one in common, that one occurring only in the former, the circumstance in which alone the two instances differ is the effect, or cause, or a necessary part of the cause, of the phenomenon.*

The method of residues will be seen to be a carrying out of the same attempt to break up complicated trains, and to fasten down the invariability of sequence upon the true particulars where cause and effect operate. It is stated thus:—*Subduct from any phenomenon such part as is known by previous induction to be the effect of certain antecedents, and the residuum of the phenomenon is the effect of the remaining antecedents.*

'There remains a class of laws which it is impracticable to ascertain by any of the three methods which I have attempted to characterise—namely, the laws of those permanent causes, or indestructible natural agents, which it is impossible either to exclude or to isolate, which we can neither hinder from being present, nor contrive that they shall be present alone.' Heat is an example of this kind of agents; we can neither divest

bodies of their heat, nor exhibit it by itself and apart from all other things; and hence the methods above alluded to would entirely fail in determining what things are connected with it as cause and effect. To meet this difficulty, we have recourse to a method named by Mr Mill the Method of Concomitant Variations—that is, in such a case as heat, we observe what effects increase as it increases, and diminish as it diminishes. The method is expressed in general terms as follows:—*Whatever phenomenon varies in any manner whenever another phenomenon varies in some particular manner, is either a cause or an effect of that phenomenon, or is connected with it through some fact of causation.* We very frequently proceed upon this method of observing the effects of the increased or diminished quantity of things, in order to see what effects they have a tendency to produce, judging rightly that if one event be the cause of another, the two will rise and fall together.

There are two kinds of complications that are beyond the reach of any of these four methods, and require a distinct treatment. The one is termed the case of the Plurality of Causes, the other the Intermixture of Effects. By a plurality of causes is meant, that it sometimes happens that an effect may arise equally from several causes, creating, as it were, an ambiguity of causation. Thus a motion may arise from any one of a great number of forces; happiness or misery is produced by innumerable agencies. In such cases, the methods above stated are somewhat nonplussed, inasmuch as it may be possible to exclude one cause and yet keep in another. A still greater difficulty is presented by the Intermixture of Effects—that is, when an effect is not single, but complex. Thus the course of a projectile is not a single, but a mixed effect, or two different effects combined into one different from either. The discovery of the cause or causes, under such circumstances, cannot be effected by the Experimental Methods. But this leads us to the consideration of a method different from any of these, which has a vast range of efficacy in scientific research, and becomes more and more powerful as the sciences advance, or as discovery is extended. It is called the Deductive Method.

The Experimental Methods suppose that we take up a subject that is as yet fresh and unexplored, or where no great general principles have been attained. They are the methods adapted to the commencement of inquiry. But when one or two comprehensive laws have been arrived at, a great deal is to be discovered by following out the application of these laws wherever they are found to operate. Thus when the law of the perseverance of moving bodies was once discovered, it was made use of to explain many motions that would otherwise have remained inexplicable: such as the rotation of the earth, and the tendency of the planets to maintain their distance from the sun. In like manner, the discovery of the general law of reaction enabled Newton to determine the cause, and even for the first time to ascertain the existence, of the fluctuation of the sun in the centre of the planetary system. By the Deductive Method alone are we able to trace the operation of that class of causes which, by intermixture, are wholly neutralised, and produce no apparent consequences whatever—as in what are called the laws of equilibrium or counterpoise.

There are three different steps in the complete working out of the Deductive Method. The first is Induction, or the determination of the general law by the Experimental Methods. The second is the carrying out of the law to the explanation of all cases where it seems to apply, and especially the tracing out of the action that would result from two or more principles acting in combination. Thus the Deductive Method applied to trace out the cause of the curved motion of a projectile, would consist in combining together the law of perseverance with the law of accelerated motion under a constantly-acting force, and in determining what would be the path that a body would describe under the two actions. The third step, which is Veri-

fiction, consists in comparing the effect deduced with the effect witnessed, to see if the two exactly agree: the agreement being the proof that the laws supposed are the laws that operate in the case. When Newton arrived, by induction, at the law of universal gravitation, and found that it decreased as the square of the distance increased, he applied this deductively to explain the attachment, or perpetual fall, of the moon to the earth. He calculated what would be the amount of the moon's deflection, supposing gravity were the cause of it; and then compared this calculated amount with the observed amount, and found a perfect coincidence. The same process he applied successively to the planets, and proved that each of them was detained from running off in a straight line through space by its gravitation towards the central sun.

Sometimes a law is assumed to exist for the sake of trying how it would explain appearances, although no such law has been discovered by a regular inductive process. This is what is called making a *hypothesis* or assumption. If, on trial, the assumed law is completely verified by agreeing with the facts, this of itself may be a reason for believing it to be a true law of nature. Thus, for example, Dalton's doctrines of atomic affinity were at first mere suppositions, or hints thrown out for trial and experiment; but it turned out that they had been so successfully conceived, as to stand the test in every instance where they were confronted with the actual phenomena.

The laws thus employed deductively, are the most general or comprehensive laws of nature, or the statements of what happens through the entire range of appearances that nature has connected with a single cause. At all events, they are the most general laws that man has been able to discover; they, moreover, refer to the smallest and simplest trains or threads of causation, or to the indivisible sequences of events. Thus the law of gravitation expresses the simplest train of causation that can be conceived; there are the fewest possible circumstances or conditions that can be mixed up in the production of any effect. This remark is necessary, in order to distinguish ultimate laws from derivative laws, where additional circumstances are introduced which make the thread more complex, and the case more limited in its application. Thus the law, that the planets move in ellipses, is a derivative law, involving the operation of two ultimate laws under certain arrangements or collocations; these arrangements are, that the planet should have been projected at a distance from the sun, in a certain direction, and with a certain speed, bearing a proportion to the above-mentioned distance. As only a very few bodies comply with all these conditions and arrangements, the law of elliptic motion is more limited in its application than the more general laws of perseverance and gravitation. When such laws are got at deductively, they are called *Derivative Laws*; when got at inductively, they are called *Empirical Laws*. The law of elliptic motion was first discovered inductively by Kepler, and afterwards proved deductively by Newton. As given by Kepler, it was therefore only empirical. All inductions of complicated sequences, or trains of causation, are of the empirical kind, and have the peculiarity of being of very limited application; they must be confined to the cases where all the conditions and arrangements are strictly contained. If we observe that a draught of cold air is the cause of catching cold, the sequence is only an empirical one, and is confined to cases where certain conditions are present; and until the conditions are strictly defined, the observation cannot be stated as a general fact even of the empirical kind. Many of the assertions made in every-day life are of this undefined description. An effect is assigned to a cause, without stating the exact conditions and circumstances necessary to insure the sequence.

When we turn from the Inductive Problem of Causation to the other kinds of propositions—namely, Co-Existence, Order in place, and Similarity—we find a somewhat different process of invention and proof re-

quisite. The most important class of propositions of co-existence are such as assert the properties of kinds, or the attributes that always accompany one another in the objects presented to us in nature. Thus when we affirm all the properties of gold, iron, oxygen, oak, horse, man, we propound propositions of co-existence. These must be sought inductively, and proved by the method of Agreement alone; neither any of the other Experimental Methods, nor the Deductive Method, is applicable. They are also peculiar in not being amenable to any great comprehensive generalisation, like the law of Universal Causation. We can never, therefore, have anything but a cumulative proof of such coincidences—that is, a proof founded on a long series of confirmations, with the entire absence of any exception.

On the propositions of Similarity mathematics are founded. For an affirmation of likeness, the ultimate appeal must be to the senses, and personal experience. When we say three and four are equal to seven, we mean—if the aggregate named three is put along with the aggregate named four—the joint effect is the same as the effect of the aggregate named seven. The truths of geometry are derivative laws, where order in place is one of the conditions or circumstances: the ultimate laws being the laws of equality, or the laws of mathematics in general.

Before closing the subject of Induction, we may advert to the grounds of the credibility or incredibility of things presented to our belief for the first time, and not proved by any independent evidence of their own. When a fact is asserted that we do not know to be true or false, but which agrees with some great established induction, we may say that it is *credible*, and needs only some ordinary degree of testimony to make it actually believed. Thus if we are told that a great avalanche broke away from a snowy mountain-height, and acquired in its fall such force as to sweep away everything that stood in its course, we reckon the assertion credible, because it is merely an instance of the working of a great natural power. But when it is alleged that the spectres of dead men come and tell secrets to the living, we call the assertion incredible, because it contradicts all the ascertained laws of things, and is not supported by any one generalisation, or any of the usual habits and proceedings of the world. We are so accustomed to the fact, that all nature's operations are on the great scale, and are to be found recurring in many different circumstances, that we are entitled to look with suspicion upon any isolated phenomenon. Such phenomenon is not accounted worthy of being entertained until it is shown that there are more of the same character to be found, or that it can be brought under some of the previously-established generalities of nature.

#### THE HIGHER ABSTRACTIONS.

The inductive determination of the ultimate laws of nature, or of the indivisible threads of cause and effect, requires in the great majority of cases that the phenomena should be viewed, not in their ordinary aspect, but through some artificial representation suitable to their inmost nature, or to the mode that they are linked together in the order of causation. Thus if we desired to ascertain the precise cause of the heat given forth by burning coal, or the single indispensable antecedent of this effect, we should find that in order to fix upon this antecedent, it is necessary to acquire a set of entirely new notions respecting the substances concerned. One important material in the act of combustion is invisible, and cannot be represented to our minds except by a complicated train of associations: moreover, it has to be singled out of an aggregate of other invisible matters, and to be defined as having peculiar properties, which must also be conceived by the understanding, as they cannot be witnessed by the senses. To ascertain that the combination of a particular gas called oxygen, with the black particles of coal, is the antecedent of the production of heat, demands a very great amount of previous preparation, in order to ren-

der visible to the mind materials and processes that are invisible to the eye.

The possibility of making inductions as to the laws of phenomena, requires that none of the circumstances or agents in a given case are hidden from the view, either by their natural obscurity or by their being accidentally out of sight. Hence a great part of the labour of discovery has consisted in obtaining the indirect knowledge of the invisible agents and modes of action that occur in the world.

Of the things that elude our senses, the first to be noticed is the whole class of gaseous bodies. The atmospheric ocean is the type of these. In the seventeenth century, the mechanical characters of this mass of matter were brought to light. Toricelli and Pascal proved that it weighed or pressed on the earth the same as solid bodies. It has also been shown to be a self-expansive mass, or to be made up of mutually repulsive particles, which tend to fly asunder to the utmost limits allowed them. But to represent these properties to the mind, we require to call in the aid of comparisons and types from the visible classes of things; and if such comparisons are perfectly correct to the extent that we employ them, we can depend upon all explanations made through their means.

Another very important class of things that do not show themselves directly to the senses, is the phenomena of the attractions and repulsions that subsist between material masses and particles. These cannot be seen by the eye except in the movements that they produce: they may be felt by the muscular sensibility, as forces or powers, but this feeling gives no assistance to the scientific conception of them. The ultimate forces of adhesion and repulsion that reign among the atoms that make up the larger masses of matter, are exceedingly difficult to ascertain and to represent to the mind; and the only means we can adopt with them, is to imagine each particle as a visible mass, and to conceive the situation and attachment or repulsion of this mass to some second mass, and so on till we have figured to ourselves as many as will make up a fair specimen of the aggregate in question.

The subtle agencies named heat, electricity, magnetism, and chemical affinity, are of the same invisible kind: they can only be conceived as embodied in certain actions of visible substances. The effects that they have upon such of our senses as they act upon, give us no key to their real character and position in the links of causation established in the world; on the contrary, these sensations give us an entirely false clue when we attempt to search into the hidden course of things. Thus our feelings of heat, or the action it exerts on our sensitive frame, stand in the way of our investigation of the ultimate laws of its phenomena; and we require to cast these feelings aside, and trace its workings through the higher senses and the reason.

The agency of light that reveals so many other things, is itself the most inscrutable of all known phenomena. The laws which regulate its action are not written on its superficial appearance: and the little that is known of it has been acquired by very roundabout efforts of the understanding. Newton, to express the fact of the solar rays producing different colours through a prism, had recourse to the notion that the white ray is a compound of seven coloured rays, which seemed to suit the appearances so far, but cannot be said to be rigorously applicable.

In human affairs it is often equally difficult to present to the eye the real powers or trains of causation that govern the facts. The sequences of the human mind cannot be seen except as shown in outward actions; and there are often many intermediate links lying between two successive outward appearances. These intermediate links must be imagined by the help of some circumstances suitable for embodying them; and the invention of these appropriate representations is a part of the process of the scientific investigation of the mind. Thus the laws of intellect are expressed under the figure of the association of ideas; and different

kinds of association are pointed out and discriminated under the designations of Contiguity, Similarity, &c.

This grand operation of passing from the superficial to the deep aspects of natural phenomena, and of finding artificial representations of such things as have no sensible aspect, has been generally styled Abstraction, or the formation of Abstract ideas; but the ordinary acceptance of this phrase scarcely extends so wide as the things we have now alluded to. We have already explained the more limited view of abstraction, and shown it to consist in the determining and expressing of the feature common to a number of things that are felt to have some similarity. This feature may be represented in many ways—as by a specimen chosen as an average of the whole, by a diagram, or by a descriptive definition. When any laws of causation connect these classes of things with other things, the determination of the common ingredient is essential, in order to state the ultimate or indivisible train of sequence. Thus if we say that the burning of coal causes heat, we must find the abstract idea of burning, or the fact common to all cases of the action; and this common fact will be the true antecedent of the evolution of heat.

The creation of good representative ideas of the obscure phenomena of nature, is one of the most difficult efforts of scientific genius, and is totally distinct from the power of experimental inquiry. It requires a peculiar boldness and felicity of mind, which belongs to but a very small number even of such as expressly devote themselves to the study of science. It was great in Newton, in Lavoisier, and in Dalton; and accordingly they gave a vast impulse to human thought, and opened up many new outlets of experimental investigation. But every now and then experimental inquiry feels the want of some great new conception to grapple with, and express, a set of subtle and complicated appearances, that cannot be brought under the dominion of law for want of this very thing.

One of the greatest examples of a true abstract idea, which is at the same time a great artificial conception of what cannot be conceived properly by means of the superficial aspect of the cases where it occurs, is the idea of polarity, or of a force which never exists except double, there being always two opposing forces joined together in the same mass. In the instance of the magnet, the character of the force is more directly apparent than in any of its other forms; but even in this instance there are appearances that contradict it, and prevent its being entertained by the mind. It is only by a very gradual operation, where experiment has been combined with the exercise of thought, and by the trial of many modes of conceiving and expressing the great hidden fact of magnetical and electrical phenomena, that the representative or abstract idea of polarity has been gained by the human mind. The experimental methods alone are helpless in such inquiries; the creative and constructive intellect must work in company with experimental inquiry, in order to bring the understanding face to face with the things that are not revealed to the ordinary senses.

There has always been in the world a recognised classification of things called 'just' and 'justice'; but for scientific purposes, it is necessary that some representation of the feature common to all such things should be got at by the comparison of instances, and by the operation of the constructive intellect in shaping a form of expression applicable alike to all.

The higher order of Abstractions obtain their expression by the putting together of Abstractions of an inferior order. Thus the definition of 'justice' would involve the simpler idea of 'equality' in some shape or other. So Mr Mill, in his definition of Property, makes use of several ideas that must be supposed to have been previously defined and settled, or that adequate representations have been already constructed for. Property, he says, in substance, involves the right of each person to the free use of whatever they have acquired by their own labour, or obtained by free gift or fair agreement from others who have so acquired it. The terms 'right,'

'free gift,' 'fair agreement,' are abstractions supposed to be previously settled and understood, otherwise the definition is insufficient. But it is by using one class of clearly-represented and well-defined ideas from which to construct others, that all the progress of human thought is achieved.

FALLACIES, AND THE DISSECTION OF EVIDENCE.

A few observations on the nature of the more common fallacies, will serve to extend the illustration of the principles and ideas that have already been advanced. There are various classes of fallacies, some of which may be enumerated as follows:—1st, Misconceptions arising from the suggestions of uncultivated human nature; 2dly, Fallacies consisting of errors in, ratiocination or deduction; 3dly, Fallacies of bad induction, or violations of the Experimental Methods; 4thly, Erroneous abstractions; and 5thly, Fallacies arising from the defects and misuses of the instrumentality of reasoning—namely, Language.

We have sufficiently discussed the difficulty that the human mind experiences in getting at nature's own point of view of the trains of causation which support the movements of the world. The first impressions of outward things upon the mind are very far indeed from the correct impressions. In the first place, the appearances presented to the senses are often the reverse of the fact, as in the case of the heavenly motions. In other cases, we are led to believe that things are where they are not, as in the way that we are misled by the refraction of light. Our feelings of what goes on within ourselves often suggest an exceedingly false view of the reality. For example, the feeling we sometimes experience of a rush along the nerves, gives us the belief of an actual fluid motion taking place through the body. Our feeling of weight or gravity renders it very difficult to admit the notion of the antipodes, and of the round form of the peopled earth. In the next place, we have very strong instincts, that pervert our views of nature still farther. We are very apt to suppose that what we see and experience is the true type and resemblance of what we do not see, or that nature works everywhere exactly as with us. Having no means of conceiving the unseen except through the seen, and being apt to believe that our conceptions of things correspond to the things themselves, we are led to assume that particular attitude of mind termed narrowness of view. Hence the discredit thrown upon the statements of the early travellers respecting remote countries, such as China, Abyssinia, and aboriginal America. Another inveterate prepossession of human nature arises from the notions that we form of force, power, and causation, arising from our own sense of effort, action, and resistance. We firmly believe that the activity and motions of the world are carried on by some gigantic personality, in exactly the same way that human beings go through their various operations upon the outer world. There is hardly any fallacy so completely opposed to the truth of things as this. The active agency of human beings, in moving matter from place to place, always implies close contact with the things acted on. The great peculiarity of natural powers, is their acting through distance, or with intervals of empty space between the agent and the thing acted on. Gravity extends from heaven to earth, or through distances of millions of miles. Heat and light are equally remote in their influences. But in the first consideration of these powers, the idea of close contact, derived from human experience, was so overpowering, that it was considered impossible that these distant actions could be maintained without some medium extending all the way from one of the bodies to the other. This is the real origin of the doctrines of an ethereal fluid pervading space, to exercise the powers of gravity, light, and heat. But for the misleading influence of our own sense of force, the facts would have been at once assumed as the ordinances of nature, that one body can gravitate to another through empty space, and that one body can heat or light another apparently in the same way; and

we would have been content to ascertain what relations these actions had to distance, to the nature of the bodies, and to the other circumstances concerned in producing the effect. The human race is not yet emancipated from this fallacy.

The fallacies of erroneous ratiocination or deduction are what are treated of under the scholastic or syllogistic Logic, which professes to lay down all the correct forms of the relation between premises and conclusion. The defect of this logic is in stopping short where it does, or in confining itself to a very small portion of the region of fallacy. When an argument is presented to our consideration, as bearing out some particular conclusion, it may often be necessary to trace back the inductions and abstractions that the propositions are made up of, as well as to see that these propositions bear out the conclusion. Thus let us suppose that the following argument were used against suicide: 'Suicide is an unsocial act, therefore it ought to be treated by society as an offence entailing disgrace upon the memory of the individual.' Like all other steps of deductive reasoning, this must consist of three different propositions, two premises, and a conclusion. One of the premises, called the *major*, must be a general assertion or affirmation, which must contain the *predicate* of the conclusion. Thus in the present case, the major premise is, 'All unsocial acts are offences entailing disgrace upon the individual committing them.' The minor premise contains the *subject* of the conclusion, and is in this case, 'Suicide is an unsocial act.' The conclusion to be established is, 'Suicide does or ought to entail disgrace on the actor.' Now, as far as the form of the reasoning goes, this is perfectly correct. If the first and second affirmations or the premises are true, the third is true likewise: a scholastic logician could find no fault with the argument. But it is clear that we ought not to be content with this; we must carry our scrutiny into the propositions themselves—considering each of them to involve an induction or deduction, and two abstractions; and we must see that these processes have been correctly performed, or whether they can be verified by the admitted facts of the world. If we take the major premise, 'Unsocial acts are punishable offences,' we find ourselves called upon first to ascertain the exact definition of the class of things here called unsocial acts, or to put into some less ambiguous description the acts meant. Now when we cast our mind about on the actions referring to society, we find that there are some directly hostile to social interests; that there are others quite indifferent; and a third class that are not hostile, and are yet not indifferent, simply because men choose to put an artificial importance upon them—such as the observance of conventional ceremonial. Now if unsocial acts mean breaches of the laws enacted for the common interests of society, the argument will have a totally different turn from what it would take if we mean by these acts things that society has no real concern with. It would be admitted, without further discussion, that antisocial acts are rightly punishable by society. If we were now to pass to the minor premise, 'Suicide is an unsocial act,' meaning thereby an act hostile to the interests of society, a new scrutiny would have to be commenced as to the truth of this conjunction. The terms of the proposition being clearly settled, we have to see whether it agrees with the facts of social workings, that suicide is opposed to any one great social interest, or whether, among the consequences or collaterals of this particular act, there is to be found any one or more that conflict with the good of human society. This stage of the discussion plainly involves an examination of the actions and reactions that occur among associated human beings, or of the influences exerted by one man upon his fellows, through the common bonds that unite each to all the rest. We must apply to the mass of social facts the experimental and deductive methods, with a view to determine all the links of causation established in this region of things. The natural method of proceeding in an in-

stance like the present, would be in the first place to enumerate all the accompaniments that we can find connected with the act of suicide in general; that is, with all acts of suicide, or with the great proportion of them. In the second place, we should have to determine whether any of these accompaniments were among the things that have an antisocial character, or obstruct any of the general interests of society. Nothing less than such a procedure as this is sufficient for the determination of the question raised. But it is obvious, that by going through this process for one question, we will necessarily settle a number of points that will serve for many other questions. Certain general ideas will have received clear definitions, and certain propositions will be inductively or deductively established, and will be so many additions to the stock of human knowledge and certainty. This is the tendency of all genuine studies, or of every decision that is come to after a due course of inquiry and examination under the guidance of sound logical principles. All decisions made in any other way are labour expended in return for error and delusion.

From such an instance as we have now given, it will be seen that fallacies may lurk in the deductive, inductive, and abstract steps of an inference, one or all; and hence the reason for adopting these designations as the heads of a classification of fallacies. An error must exist whenever any one of these processes is insufficiently performed; and to rectify the error, we must revert to the rules for their accurate performance, which are founded on what we have seen to be the essential characters of each process.

A very large class of fallacies is included under the Abuse of Language, which is the instrument of the greater part of our reasonings, and of all of them that can come under the province of Logic. Many of these fallacies are not to be distinguished from such as come under the other heads. But Language has certain tendencies of a fallacious kind, that make a class apart from all the rest. It is apt to stand in our minds in the room of the facts that it expresses, and thus to obstruct our view of the realities of the world. Being a powerful instrument for fixing ideas in the mind, it gives equal aid to the false and to the true, and thereby perpetuates the reign of whatever errors have once been clothed in words. We have formerly seen that the use of a general name is a perpetual affirmation of similarity among the things to which it applies. Hence if a wrong generalisation has been made in any case, or if a certain number of things have been falsely declared to have a common feature, the general name is the instrument of circulating and maintaining the falsehood in the world. Another evil that arose out of the nature of Language was connected with the tendency that there is to recognise the separate existence of whatever has a separate name. Hence arose the doctrine of realism, or the notion that abstractions had a distinct and dependent existence, and that concrete objects were actually formed by the union of their abstract constituents. Thus wisdom, virtue, government, roundness of form, hardness, which have each a distinct name, and are distinguished by the human intellect, were thence supposed to have distinct existence, or could be found apart from the complex objects that we call 'wise,' 'virtuous,' 'round,' 'hardness,' &c. The great scholastic controversy of the middle age turned upon this question, and it was not till the seventeenth century that it was generally admitted that these abstractions had no more than a mere intellectual or verbal distinctness of existence.

The forms of Language are liable to mislead us in the way of confounding verbal with real propositions or definitions with affirmations of principles. The definition has the same verbal form as the proposition. 'A triangle is a three-sided figure,' and 'A triangle has two of its sides greater than the third,' have the very same structure of enunciation; but the one is a definition, or a declaration of the nature of the thing that we name 'triangle;' the other is a proposition, or an

affirmation of the conjunction of two things—namely, the triangular form, and the fact that two of the sides taken together are greater than the third. The definition is not a thing of affirmation or denial in the same sense as the proposition; what it affirms is not a law of nature, but the conjunction of a name and a thing; and the truth or falsehood of the assertion is not dependent on any facts of nature, but on human convention. The mistaking of a verbal for a real proposition, owing to the frequent similarity of their form, is one of the most common fallacies arising out of the nature of Language.

#### THE LOGIC OF THE SCIENCES.

The general laws and abstractions that are arrived at by the methods above described, are collected together under separate heads, according to the subjects to which they relate; and each collection of generalities is called a Science. When the aggregate is formed on the plan of taking in all that belongs to one distinct department of natural phenomena, we have a *pure* or an *abstract* science. Thus the collection of laws that has reference to the natural group of organised and living bodies makes up the pure science of Life, which has been termed *physiology* or *biology*. But when the truths of nature are brought together from different regions of phenomena to serve some practical purpose, or to explain some local appearances, the aggregate is a *mixed* or *concrete* science. Thus in the science of medicine, the laws of physical, chemical, and physiological actions are brought to bear upon the practical end of curing disease; and in the science of geology there is a similar gathering of doctrines to explain the complex appearances of the earth's crust. The classification of the abstract sciences will therefore follow the different kinds of action that are made use of in nature; while the mixed and concrete sciences will be as various as the practical objects of life, and the local contingencies of different modes of operation.

M. Auguste Comte was the first to carry out to the full this great distinction among the sciences, and to give a rigorous definition of the abstract division. The abstract sciences, according to him, are Mathematics, Astronomy, Physics, Chemistry, Biology, and Sociology, corresponding to the six primary or fundamental classes of natural properties and actions. Mathematics has reference to number, quantity, and extension; Astronomy is the science of gravitation; Physics the science of cohesive masses of matter; Chemistry includes the atomic affinities of unlike substances; Biology treats of the laws of living beings; and Sociology has reference to the structure of human society. The order now given has been shown by M. Comte to be the true natural order and succession of these sciences, being the order of their first discovery, as well as the order of their easy comprehension and natural dependence. At present, in speaking of the general or abstract sciences, we shall prefer to include Astronomy with Physics, and to detach the science of mind from the comprehensive branch relating to living beings. The arrangement will then stand thus: Mathematics, Physics, Chemistry, Biology (Life), Psychology (Mind), Sociology (Society). These lay hold of six different groups or classes of natural appearances and laws; and there is not, as far as we know, any fact, process, or operation in the world, that does not come under some or other of these six heads. The knowledge of Mathematics, Physics, Chemistry, Vegetable and Animal Physiology and Anatomy, the Human Mind and Human Society, is the knowledge of the whole of nature. If we are versant in all the laws and abstractions of each of these six subjects, we are prepared to understand every event that can possibly occur in the world. We may not have carried out these laws to all possible cases of practical and local application; but we are prepared to comprehend and appreciate every instance of their being so carried out.

The natural dependence of the abstract sciences in the order now given may be explained thus:—Each one is dependent on all that lie above it, and is a basis of

all that lie below it; and as we proceed from the top to the bottom of the list, we pass from the most simple and most universal properties and laws to such as are more complex and limited; in other words, there is a connection of dependence and of generality: the first sciences are the least dependent and the most general, the last are the most dependent and the most special. *Mathematics*, which treats of magnitude and numerical properties and laws, extends to all the materials and operations of the universe; everything that exists has the property of being more or less, and is subject to the laws of quantity. The phenomena of all the other sciences come under the scope of mathematics, and often depend directly on its doctrines, while these doctrines are themselves quite independent of all other properties. *Physics* and *Chemistry* would be completely upset if any of the Arithmetical or Geometrical laws or rules were to change; but no alteration in the physical or chemical properties could affect the numerical properties of things: three times six would be eighteen, and the binomial theorem would be eternal, whatever revolution was produced in the laws of heat or atomic proportions. But if we take the *physical* properties of matter, which include the laws of the aggregation of bodies, and the four agencies of gravity, heat, electricity, and light, we find that these are dependent on the numerical properties of matter, and independent of its chemical properties. Physical properties are super-added to form and size, and vary with these attributes, while chemical properties are a subsequent addition. The *chemical* powers are modified by physical states, but physical powers are not modified by chemical characteristics. Gravity acts upon all bodies the same, whatever their chemical affinities may be, and would continue to act though these were abolished. In like manner, the *vital* properties of matter are modified by the numerical, physical, and chemical properties, without reacting upon these so as to alter their character. So the laws of *mind* are still more complex and dependent, and so much the more limited and special. Not only all matter, but all possible or conceivable existence, shows mathematical attributes; all matter shows physical characters; a certain portion of matter is placed under the sweep of chemical combinations and decompositions; a select fraction of this is organised into the forms of life; and a still more limited portion is employed in connection with the appearances of mind. Unless we know all that can happen from numerical combinations, we cannot explain physical phenomena: we need both numerical and physical, as well as chemical, knowledge to comprehend chemical phenomena; and all the three are required as a preparation for the science of life. Any attempt to explain one class of properties while we are in ignorance of the previous classes, is an inversion of the order of things, and is nearly as hopeless as the ascent to a height without passing through the intermediate spaces. The laws of phenomena obtained previous to the understanding of all that should precede such phenomena, can at best be but empirical laws, and must be strictly limited to the circumstances where they have been observed. The laws of physiology are almost wholly empirical, owing to our imperfect acquaintance with the physical and chemical operations concerned in the vital processes.

Each of the six fundamental sciences has a logical character of its own—that is to say, the method of proceeding for establishing the general laws and properties that make up any one science varies with the nature of the phenomena included in it. Hence the cultivation of each confers a distinct and separate discipline on the intellectual faculties. Astronomy, for example, carries to the highest perfection the two processes of observation and deduction. In no other science have the means and devices of accurate observation been so much improved; and, on the other hand, as all the phenomena can be deduced from the ultimate laws of mechanics, combined with the law of gravitation, with the most complete numerical accuracy, the science affords a perfect instance of the deductive method of

arriving at truths. If we pass from Astronomy to terrestrial Physics, including the laws of solid, liquid, and gas, heat, mechanics, hydrostatics, optics, electricity, &c. we find ourselves in the domain of experiment, which is entirely inadmissible in the celestial physics; and the cultivation of the experimental devices, of excluding and including known causes and circumstances, is in the highest degree practicable. For the last two centuries, Physics has been the great field of experimental research; and it may be said that the art of accurate experimenting was first acquired in this field, although it has since been extended to other branches. The experiments that decided the weight and pressure of the atmosphere, Newton's experiments on light, the researches of Dr Black on latent heat, and the very extensive experimental inquiries that have been made within the last seventy years on Electricity, may be alluded to as illustrious not only in the history of Physics, but in the progress of the human reason. Chemistry is, like Physics, a highly experimental science, but its distinguishing feature is its having to provide for a classification of the materials of the globe according to their composition. As it shows that the earth consists of about sixty simple substances, which have almost an infinite capacity of combining into compounds, it has to ascertain the circumstances attending on all combinations and decompositions, and to make a regular classification of all the resulting bodies according to the simples that make them up. For this it has to invent a grand system of nomenclature and arrangement, such as is not required to the same extent in any other science, but is not without its use, apart from the immediate purposes of chemistry. The science of life requires, as its peculiar auxiliary, a system of classification by genera and species, and carries this device to its utmost perfection. In like manner the sciences of mind and society have their peculiarities of method, or their special contributions to the logical cultivation of the human intellect. The lessons that all the leading sciences agree in cultivating are—the supremacy of reason over sense and instinct, and the necessity of bringing all assertions to the test of rigorous proof. We shall now advert to the fundamental sciences, with the view of bringing prominently forward the peculiarities of the classes of phenomena which they severally include:—

The science of *Mathematics* is divided into two great branches—the one Abstract, including Arithmetic, Algebra, and the higher or transcendental Analysis; the other is called Concrete, and takes in Geometry and General Mechanics. The Abstract branches consider number and quantity in general without reference to any special things numbered or quantitatively estimated. The Concrete branches refer to peculiar kinds of quantity: the one, Geometry, referring to space and the forms of things occupying space; and the other, General Mechanics, being devoted to motion and the things necessary for expressing motion—namely, space and time. Mathematics proper, however, is usually considered to terminate with Geometry.

Arithmetic reposes upon the ten figures and the decimal notation. Without inventing names for the successive numbers, and adopting some principle for expressing shortly and systematically the higher sums, no nation could ever progress in Arithmetical calculation, or in the arts and sciences where it is much required. The chief business of Arithmetic comes to be the reducing of all possible combinations of numbers to one universal form, or to the gradations of units, tens, hundreds, &c. Thus the multiplication table, which contains the fundamental laws of the science, merely serves to show how to reduce products of any two numbers to a product where ten shall be one of the factors. 'Nine times seven are sixty-three,' means that if a row of seven be taken nine times, the sum-total will be the same as six rows of ten and three over. When all products are reduced to the one decimal scale, their comparison among themselves becomes much more easy than if they were kept in all variety

of scales. If we wish to compare nine times six with eleven times five, we find it most convenient to bring both into products of tens, by making the one fifty-four, and the other fifty-five.

Algebra is a higher process than Arithmetic, and has been defined the reduction of equations. Its main peculiarity lies in putting two different complex expressions that are equal over against one another, and then in operating upon the two by adding, subtracting, &c. the same things from both, so as still to preserve the equality, and at the same time to bring the equation to some simple form that will give the value of a single ingredient of the original expression. Thus an easy question in Algebra would be to find a number which, when added to its square, would give 56. Here an equation would be formed by putting 56 on one side, and on the other an expression of a number added to its square, the number being represented by a letter (such as  $x$ ), and the business would then be to operate on this equation till it is reduced to another with nothing on the one side but the representative of the number itself, in which case the other side would give the actual number in arithmetical figures. The higher analysis was invented by Newton and Leibnitz to solve such questions as computing the areas and circumferences of curved surfaces, and the spaces and times of accelerated and retarded motions.

Geometry treats of the laws and properties of lines, surfaces, and solids, straight or curved. It has two branches—Special and General Geometry: the one is exemplified in Euclid, who treats each figure by itself in succession, as in triangles, circles, &c. General Geometry treats whole classes of figures at once by stating them in Algebraical Language.

General or Rational Mechanics lays down the first principles or laws of motion, and applies these to calculate the effects of all possible kinds of forces, single or combined. It makes an important distinction between forces that are counterbalanced so as to produce rest or equilibrium, and forces productive of movement; this gives rise to two branches named *Statics* and *Dynamics*. To determine the path of a projectile is a simple mechanical problem: two forces are given, which, separately, would produce certain known effects, and the question is to find the effect of both acting together.

*Astronomy* is the link between General Mechanics and terrestrial Physics: it is a case of motion and forces where the natural agent, gravity, is brought into the question. Experimental induction having traced out the law of gravity as the power concerned in keeping the heavenly bodies together, the principles of mechanics enable us to compute, by the help of mathematics, all the consequences of this agency—that is, if we find that the moon is acted on both by the earth and by the sun, with a certain energy depending on the mass and distance of each, it is possible to calculate what course she will describe under the two actions, and where she will be at any specified time. Or the great problem of Astronomy may be stated thus: Given the present position of any one body in reference to all the others that act upon it, and given the effect of each of these for a certain instant of time, and also the body's own proper movement, to find where it will be an hour, a day, or at any time, hence; this, it will seem, is only a more complicated case of the question as to the path of a projectile. There are certain terrestrial actions—as the Tides—which come under Astronomy from their being caused by distant gravitation.

The first branch of *Terrestrial Physics* is commonly termed the Properties of Matter, meaning thereby the laws and peculiarities of the aggregation of matter into solid, liquid, and gas. The next agency that we come upon after gravity, is the cohesive power that binds the atoms of bodies into masses of more or less firmness of structure. It requires us to recognise as a first principle of the composition of the material world, that all its substances are made up of exceedingly small particles or atoms, which are gifted with powers of mutual attraction and repulsion; and under the action

of these powers become, according to the way that they happen to be adjusted, solids of more or less compactness, liquids, or airs. These powers of adhesion are very varied and unequal, and in this respect contrast with the uniformity and regularity of the gravitating force. They not only differ in different substances, but they differ in the same substance, in consequence of there being a grand pervading energy of nature supplied in the first instance by the sun, which is able to overrule and modify them. In fact, the adhesion of atom to atom in a solid or liquid is the result of a natural attraction between the particles resisted up to a certain point by a repulsion infused into them from without, by the all-pervading influence that we term Heat, and which we speak and think of as a subtle substance or fluid like air, but which is more properly a grand relation of mutual action between all material bodies, whereby they affect one another's atomic constitution whenever a peculiar balance or equilibrium is disturbed. It is very inconsistent with our rude instinctive notions of force, to suppose that because some change has come over the interior attractions and repulsions of one body, a set of analogous changes will be propagated to all bodies in the neighbourhood till some state is given to each consistent with the repose of the whole. But having once admitted the principle of action through distance, without any intermediate filling up of the interval between the bodies, there is no reason why we should not prepare ourselves for finding other cases of the same kind of action though varying in the details.

The first division of *Terrestrial Physics* being the *Laws of Material Aggregation*, and the second the *Laws of Heat*, it is usual to follow these up with *Practical Mechanics*, *Hydrostatics*, *Pneumatics*, and *Acoustics*, which involve no new first principle not contained in the previous departments. There, then, remain the two subjects of *Electricity* and *Light*, each involving a distinct natural agency. Electricity has now been completely generalised, and shown to be a wide ranging power of the *polar nature*, which puts on many forms according to its material connections, but invariably maintains the character of a polar or double force. There are no less than six or seven subordinate branches, falling under two grand divisions, which are distinguished by the terms *Statical* or *Reposing*, and *Dynamical* or *Current Electricity*. The first of the subordinate branches is the oldest—namely, *Magnetism*, where the polarity is most conspicuously exhibited, from its acting on large masses of iron or other magnetic metal. The second of the Statical branches is *Frictional Electricity*, or the electricity of the common machine. This branch was created in the latter half of last century by Franklin and others. The first of the Dynamical branches is termed *Voltaic Electricity*, or the excitement of the voltaic pile, which first showed the close connection between electricity and chemical action. Next follow *Electro-Magnetism* and *Magneto-Electricity*, being the laws of the derivation of magnetism from electricity, and conversely of electricity from magnets. *Thermo-Electricity* is the derivation of the excitement from heat, which completes the proof of the connection between these two great natural powers. In addition to all these, electricity has to be considered in its relation to animal and vegetable bodies, as being both produced and expended within the living organism.

The subject of *Light* has, in some of its bearings, been set forth with great distinctness, as in all the mathematical relations of its incidence, reflection, and refraction on surfaces; but as to its origin and ultimate action on the surfaces that it renders visible, and on the receiving surface of the eye, nothing is yet known. Most bodies, when heated to some given temperature, become luminous; but it does not appear that any of their heat is wasted in supplying the rays of light; so that although an undoubted connection subsists between light and heat, it is totally different from the relation of heat to electricity. Hot bodies give light

in addition to their heating power; but if such bodies are made to yield electricity, their heat is consumed or wasted in the act of being turned into electric excitement. No means has yet been found of investigating the changes wrought in the surfaces of bodies by the action of light; but the invention of the Daguerreotype seems to be a beginning in this direction.

**Chemistry** is related to Physics through Heat and Electricity. It treats of the circumstances and laws of the combination of simples into compounds, and the resolution of compounds into simples. The kind of combination here meant is something quite different from mechanical mixture, as when sand and lime are put together to make mortar; it is different even from solution. It takes place in fixed proportions, and ends in producing out of two substances a third so different from either, that it could never be suspected to be made up as it really is. Chemical combinations likewise give forth heat, or produce that general disturbance in the atomic condition of surrounding bodies, that goes under the name of raising their temperature. The chemical properties of a substance mean its power of entering into combinations, or causing decompositions, with other substances; a body standing alone can exhibit no chemical relation; hence the prevalence of the idea of binary combination in chemistry, although there is no reason to suppose that three things may not combine together in the same act as well as two.

Combination and decomposition being the great facts of chemistry, it became an accurate science when the laws of these processes were ascertained by Dalton. A great part of chemical research during the last forty years has been devoted to finding the simples that go to make up the complex substances of the globe, the possible combinations of these simples, and the numbers to be assigned to each as indicating the proportion that they bear in combining with one another. Devices have had to be invented for bringing about combinations and decompositions in all possible cases, as it often happens that these cannot take place in any obvious or direct way. Chemistry is usually divided into Inorganic and Organic. Organic Chemistry treats of the chemical composition and actions of the substances that are formed in the vegetable and animal processes. As distinguished from the materials presented by the mineral and inorganic world, these substances are all very complex. Sugar is by no means an extreme example of organic complexity of combination; but one of its atoms contains twenty times as many atoms of simples as an ordinary inorganic acid, such as oil of vitriol. The products of the animal tissues are far more complex than even this. The number of substances in nature that are chemically distinct may amount to hundreds of thousands, giving thus a prodigious choice for human purposes when once they come to be properly known. There is scarcely a single vegetable or animal species that does not yield some peculiar and characteristic chemical compound.

Organic Chemistry is the link connecting chemistry with the science of living bodies. It is necessary to know fully all the physical and chemical properties of the tissues and substances used in vegetable and animal life, in order; by their separation according to the experimental method of residues, to ascertain what functions are due to vital powers and properties, rightly so called. Thus the act of digestion is performed partly by the physical action of solution, and partly, it would appear, by chemical combination; but when these are allowed for, there still remains a portion of the effect to be ascribed to a power different from either.

The general science of *Life* is divided into Vegetable and Animal Anatomy and Physiology. Anatomy is understood to mean the description of the organised structure of living bodies; and Physiology describes the processes and changes that go on within them.

The great foundation peculiarity of an organised structure is, that it is made up not of atoms, but of cells, which have the power of breaking up and giving birth to other cells from a nucleus in their interior or

in their walls. These cells adhere together, and form tissues, which, in the living state, go continually through the process of decay and renewal, by the operation of the bursting of old cells and the growth of new. The contact of a cellular mass with certain kinds of unorganised matter is sufficient to convert the whole of this matter into vital tissue, by making it go together into coherent cells; the principle of like producing like, or of the communication to a shapeless mass of form and organisation by the touch of what is already organised, being one of the laws of vitality.

The grand difficulty in physiological science is to explain how so small a point as the seed of a plant, or the germinal matter of an animal, can contain within itself such a definite impress as to determine exactly the character of the future expanded being. But we ought to consider, that although the whole futurity of a man may at one stage be contained in two or three cells, yet each of those cells, in comparison with the ultimate atoms that make it up, is like the whole of St Paul's as compared with a single stone; and therefore there is abundant room for its containing all the essential characteristics of the full-grown individual, although they cannot be traced even by the microscope.

The recent discoveries in anatomy go far to simplify the animal structure. Professor Owen has lately completed a most important demonstration in respect to the vertebrate skeleton, or the bony framework of all that class of animals that have a backbone, as distinguished from shell-fish and the other creatures where the hard skeleton surrounds the fleshy and soft parts. He has shown that all these animals, from the fish and reptile, up to man, are made on one pattern, varied to suit their different peculiarities; and that a fundamental or general skeleton can be assigned as the point of departure for the whole. What is still more singular, this fundamental skeleton is a repetition of the same piece from head to foot. In fact, if we take one of the vertebrae of the backbone, we have an example of the simple piece, which, by being repeated and modified, makes the whole skeleton of a man, a quadruped, a bird, a fish, or a reptile. Four vertebrae joined together, and having some of their parts more expanded than usual, constitute the head and the two arms. So that to make the skeleton of any animal, what is required first is a sufficient number of these vertebral cross pieces; and in the next place, a determination of the extent of growth that is to take place in their several parts, so as to suit the demands of the species proposed to be created. Professor Owen has been able to identify every bone of every animal of the vertebrate class with the corresponding bone of every other animal, through all their changes of form, and also to assign the portion of a vertebral cross-piece that every one of them sprung from. As regards the complicated structure of the head, Mr Owen has had the glory of completing the identification through the whole species, and of finally clearing up all the doubts and perplexities that were left hanging around the subject by the most illustrious of his predecessors. One magnificent idea may now be said to reign through this wide region of nature's works, which includes the nobler half of the entire animal creation.

As the *mind* of man is a portion of the living system, and as a special organ is devoted to its action on the framework, the study of this organ—the brain—under anatomy and physiology, might naturally be supposed to be the prelude to the science of mind. In this point of view, psychology would be the natural sequel to the general science of life. But it so happens that this is not the only way of approaching the subject of mind: had it been so, we should have been in total ignorance of the mental phenomena until within the last few years; for it is only of late that any progress has been made in tracing the laws of mind from the anatomy of its material organ. There are two other great sources of knowledge on this subject—namely, the outward appearances and manifestations of thought, and feeling, and consciousness; and the inward sense

that each individual has of what passes within himself. These have been illustrated in our previous number (71) on the HUMAN MIND.

But there can be no doubt but that the future progress of anatomical and physiological discovery will act powerfully in throwing light upon the laws and properties of mind. It is not the dissection of the brain alone that we depend on: the structure of the organs of sense and of the muscular system, which are the terminating points of the great proportion of the nervous threads, is of equal consequence. But no part of the system is unimportant in its bearing upon the thoughts, feelings, actions, and volitions of the mind. And if ever the laws of mind should be completely traced through the medium of the anatomy of the framework (a thing scarcely to be hoped for), psychology would become purely a dependent branch of biology; but in the meantime it possesses an independent existence, and it has in all ages been studied, and in some measure understood, without the help of any of the other abstract sciences that stand before it. This is perhaps the only apparent break in the strict dependence of the six fundamental sciences.

The great peculiarity of the method of psychology henceforth must be the reconciliation of the indications of the three different sources of knowledge—*anatomy, external manifestations, and consciousness.* No principle of human nature can be finally accepted, till it is verified in all the three ways.

Sociology, or the science of human *society*, comes last of all, as being most complex, or as involving all the phenomena of the previous sciences. The arrangements of society depend on the properties of the inorganic and organic world on the one hand, and on the character of the mind of man on the other. The life of men and of societies is restricted by the mathematical, astronomical, physical, chemical, and vital laws and conditions of the surrounding world, and is rendered more perfect in proportion as these are better known.

The more immediate dependence of the structure of society on the peculiarities of the mind of man, has enabled the subject to be studied along with this last from the very dawn of human speculation, and while all the preceding sciences were in their infancy. But it has been shown by M. Comte, that every advance in these sciences has been accompanied with some corresponding advance in the mode of viewing social questions; so that all history attests the existence of a real dependence under the outward appearance of independence.

The greatest simplification that has been made in the complicated subject of society, has arisen from carrying out a distinction derived from the anterior sciences; the distinction in Mechanics between Statics and Dynamics; and in Biology between the powers that maintain organic life and the powers that bring about the progress of the being from one stage to another. In society, the terms Order and Progress express the two corresponding ideas. Order means the maintenance of the peaceable workings of any one society; Progress means the advancement from one arrangement to another of a superior kind—as from the state of slavery to the state of liberty. By discussing the two subjects apart, all the questions relating to society and history are at once freed from the largest share of the embarrassments and difficulties that have always surrounded them.

The doctrines of Social Order are more particularly dependent on the laws of human nature, and are advanced in precision exactly in proportion to the accuracy of our knowledge of these laws. The fundamental idea of society being the harmonious co-operation of a multitude for the better attainment of common ends, and the first step in the working out of this idea being the setting up of a central government, or ruling power, the grand requisite of good order is *obedience* to this power. Where the government is obeyed, order reigns, whatever other evils may exist; where successful disobedience has occurred, there is disorder or anarchy. To secure obedience is, therefore, the problem of Order; and this must be accomplished by connecting the go-

vernment with some of the most powerful reigning impulses of the human mind. If the sentiment of filial obedience be very strong, and if the people can be induced to consider the supreme civil ruler as a father, they will be disposed to render him obedience with the whole force of their filial devotion. If the religious sentiment is high in a people, and if they can be made to believe in the Divine right of kings, obedience may be secured from this source. If society is so constituted as visibly to be for the advantage of the majority of its members, the sentiment of self-interest will suffice to keep up the spirit of obedience. It will thus be seen that the supports of Order are such of the mainsprings of human action as can, for the time, be brought into harmony with the principle or pretence that lies at the foundation of the existing government. Hence the character of the people is an important consideration in determining the means of securing their obedience.

Order not only implies a harmonious relation between the mass of a people and their central government—it extends to all the smaller associations included within the greater. The proper constitution of local governments, of the spiritual government, of the family, of the relations of master and servant, teacher and pupil, is a matter of adjustment according to the prevailing impulses of the individuals concerned, and no one rule can be made universal in any of the cases.

Progress, which is also termed *Civilisation*, means the advancement from one state of Order to a higher, or to a state where a superior class of the impulses and capacities of man are brought into action. When a government, based on the superstitious prostration of the mind, gives place to one recognised by the reason, on the grounds of its contributing to the well-being of the society, a step of progress has been achieved. So, when a clear knowledge of affairs in a ruler, instead of the arts of oratory, is the means of gaining a people's confidence and co-operation, the society has entered a higher stage of advancement.

The proper meaning of *Civilisation* is the application of intelligence to the improvement of the human condition. It includes all that is not derived immediately from nature; in other words, nature and civilisation together make up the whole of human existence. The instinctive capacities of men are the immediate gift of nature; the powers acquired by the use of intelligence and will, confirmed into habits, and transmitted by instruction from age to age, are civilisation. The original genius, or inventive capacity of man, is the origin of everything included in human progress. Consequently civilisation consists of as many distinct streams as there are divisions in the arts of life and the creations of the human intellect. The *industrial arts, the training arts, the healing arts, the arts and forms of social intercourse, the art of government, morality, religion, sciences, the fine arts, literature, and the art of living,* are all included in this one comprehensive designation.

But it is especially important for our present purpose, which is to consider the dependence of the different branches of knowledge, to call attention to the fact, that although we have named eleven different branches of civilisation, there is one that is at the centre of the whole, or so related to every one of them, that if we concentrate our regards upon it as we pass along the stream of human history, we shall thereby detect the very essence of what progress there may have been. This central and predominating part is *science*, meaning thereby more particularly the abstract or fundamental sciences as we have now sketched them out. Science is the perfect work of the human intellect, its highest achievement in the search after truth, and the very touchstone of its capacity to grapple with the appearances and realities of the world, and to form such conceptions as can be relied on in practice. This connection of the progress of science with all the collateral branches of civilisation, and with the great revolutions of the world, has been pointed out for the first time in all its extent in the 'Cours de Philosophie Positive' of M. Auguste Comte.

## NATURAL THEOLOGY—ETHICS.

NATURAL THEOLOGY is that branch of logical science which comprehends the discovery of the existence and attributes of a Creator, by investigating the evidences of design in the works of creation; and in an enlarged sense, it refers to the probable intentions of Deity with regard to his creatures, their duty, and conduct. It cannot but appear to every rational mind, that a subject involving such important views and considerations is full of the deepest interest, and may be made the agent of much intellectual improvement. It is incumbent on us to read the wisdom of God, and his admirable contrivance, in all that we see around us and above us, and which pertains to the universe to which we belong. Independently of the pleasure, and perhaps worldly advantage, which the study of Natural Theology may produce, it will be equally serviceable in keeping alive feelings of piety and devotion. As Lord Brougham has very appropriately remarked, 'even the inspired penmen have constant recourse to the views which are derived from the contemplation of nature when they would exalt the Deity by a description of his attributes, or inculcate sentiments of devotion towards him. "How excellent," says the Psalmist, "is thy name in all the earth! thou hast set thy glory above the heavens. I will consider the heavens, the work of thy fingers; the moon and stars which thou hast ordained."'

It is worthy of remark, as showing the depth and solidity of the foundation on which rests the existence of a supreme, intelligent, and beneficent First Cause, that the farther we push our discoveries, the more clearly are the Divine perfections exhibited. It is not merely true that, on a superficial view, we perceive the necessity of believing that a limited and changing world, such as that on which we dwell, could neither exist without being produced, nor be the author of its own existence; and that there must therefore be, beyond the range of our senses, an independent and uncreated Essence, without beginning, without bounds, incapable of change, intelligent, ever-active, all-pervading; but it is also certain that those views are not only uncontradicted, but fully established by the most minute survey of the objects within the sphere of our observation; so that he who penetrates the deepest into the secrets of nature, only multiplies proofs of that most sublime and most animating truth, that 'verily there is a God' who made and rules the universe. It is difficult to understand that strange moral obtuseness which has induced a certain class of writers to reject this; for grant but one assertion, which is—and it is not easily to be questioned—that there exist in nature indisputable traces of design, planned with wisdom, directed by goodness, and upheld and accomplished by power, and it follows that there also of necessity must have been a *wise, a good, and a powerful Designer*.

Let us suppose ourselves cast ashore upon some island previously unknown to us; we immediately proceed to examine the appearances which present themselves, in order to discover if any traces exist of human inhabitants. To ascertain if such beings there existed, it would not be necessary that they should actually be seen by us. In our wanderings we might come upon a hut bearing all the marks of occupation; we might see the roots of the trees which had been felled to form it, and other tokens of the recent presence of man upon the spot; and did we desire to discover something of their character and habits before we presented ourselves to their notice, it is most probable that sufficient data would be also afforded on which to found an opinion. Were the habitations we discovered merely wigwags, or rude enclosures destitute of the conveniences of civilised life; or were the furniture, the weapons, or the instruments in and around them such as barbarous na-

tions generally use, we might reasonably argue that we had found the dwelling of an untamed savage. But if, instead of this, we find the surrounding land trenched, enclosed, and cultivated; should we find the common articles of European husbandry, and the common utensils of a European household, we should naturally draw the inference that we had reached the abode of an emigrant, who had thus reared around him the attributes of civilised life. Much more a few additional observations might reveal to us, and enable us to form conjectures, bearing the aspect of probability, concerning the people among whom we had fallen. Now it is in this way alone that we can argue respecting the Author of all things, and discover proofs and demonstrations of a first supreme Cause. To prove that the formation of all things was the result of DESIGN, it is only necessary to show that they are in general, or in so far as we can discover, admirably suited to the uses and purposes to which they are to be applied—that their arrangement is perfectly harmonious—and that it is impossible that any chance could have thrown them together in a way so happy. To discover if this design can be evidenced or demonstrated, it is necessary to seek through the various works of creation with which we are surrounded; and the more minute we make our inspection, the more likely shall we be to perceive the deduction. If there be some departments to which our senses have a readier access than to others, and which we can therefore more readily examine, from these especially we ought to deduce our result. It may be that we shall find many things which, from the deficiency of our observing faculties, we cannot understand, nor discover the uses or consequent design which they display; but still if, in the course of our inspection, we find every part admirably adapted for a specific purpose, and teeming with the most convincing evidences of design, then we may with safety, and in the spirit of true philosophy, infer that in those objects which, from their nature and our imperfection, we cannot so completely investigate, a greater degree of light would tend to confirm the result to which our previous observations, among other things, had led us.

### DESIGN IN THE PLANETARY SYSTEM.

To the uninstructed eye, the earth which we inhabit appears on a clear night to be surrounded by a numerous host of radiant points, which, rising in the east, move majestically through the sky until they reach the western horizon, when they set or disappear; and so completely does this idea commend itself to the mind of an observer, that it requires a considerable effort to conceive how it can be otherwise. But science has taught us that this is a mere illusion, and the discoveries of Copernicus and Sir Isaac Newton have established the truth suggested by Pythagoras upwards of 2000 years before the time of either of them, that the apparent motion of the heavens is the consequence of the real revolution of the earth every twenty-four hours upon its axis; that, with relation to the earth, the sun is stationary, while the earth every year completes a journey round him; that the planets are globes similar to our own, revolving at once upon their own axes, and round the sun; that the moon is a satellite or attendant upon the earth, accompanying it in its course, and at the same time describing every month a circular orbit round it; and that to several of the other planets are attached similar moons or satellites, bearing to them a corresponding relationship.

By referring to our article ASTRONOMY, in which the number of the planets, and their distances from the sun, with other particulars, are noted, it will be seen that the earth which we inhabit is but a very small point,

even in the *solar system* (as the concourse of planets round the sun has been called), and that it forms but a part of one magnificent and resplendent whole. But to ascertain the marks of a designing mind in this mighty maze of brilliant wonders, let us turn our attention to some of those particulars regarding them with which we are acquainted; and it must be confessed that, if we are to suppose them mere masses of matter unclothed with aught bearing analogy to our vegetable productions, and uninhabited by beings either sentient or rational, it will be difficult to see why any of the arrangements connected with these bodies, so far at least as they themselves are concerned, and apart from their attractive influence upon our own world, should be either beneficial or the contrary. It is solely on the conjecture that there are organised beings on their surface to be warmed, and nourished, and upheld, that we can argue regarding such arrangements; and making this conjecture, we shall find that there are some very remarkable apparent contrivances for ministering to their comfort and happiness. It has been supposed that a planet so far distant as Uranus, or even Jupiter or Saturn, must suffer from an extreme deficiency both of light and heat; hence it has been argued that they are necessarily unfit for the sustenance either of animal or of vegetable life. But when we consider that even Uranus possesses 248 times the light afforded by our full moon, it will not be difficult to believe that, with a somewhat more acute power of vision than we possess, the inhabitants of that planet, if formed like ourselves, may be quite able to engage in employments which require considerable minuteness of perception. Besides, to compensate for the deficiency of light derived directly from the sun to this planet in common with Jupiter and Saturn, there is afforded the subsidiary benefit of several moons or satellites to reflect light upon the surface when the sun has withdrawn his beams; neither is it probable that the inhabitants should miserably perish from cold; for putting out of view the possibility that they may be formed with constitutions adapted to a more frigid climate than that of any portion of our world, we must remember that heat is not dependent altogether upon the body from which it originates, but is regulated in a very great measure by the nature of the body to which it is transmitted. Keeping this in view, the planet Mercury may be as cool, and Uranus as warm, as our own globe, although they be at such different distances from the great source of heat. This, however, can be the subject of conjecture alone; and it is only valuable as showing that we have no reason to suspect the goodness of the Creator in having placed some of his worlds in situations which at first sight might be supposed necessarily incapable of affording even the most essential accommodations to organic existences.

Of all the planets, Saturn presents us with the most singular example of design in reference to this subject. When viewed through a telescope, this beautiful orb is seen to be surrounded by a double circle of 30,000 miles distant from any part of its surface. This apparatus consists of two concentric rings, separated from each other by a space nearly 3000 miles in breadth, and moving round the planet at the extraordinary rate of a thousand miles a minute. Now there is one use of this appendage, whatever may be its other purposes, which is very apparent: it must contribute much to enlighten and beautify the globe to which it is attached; and a very little reflection will show the effect it must have in this respect. What a magnificent brilliant spectacle must these rings present to the inhabitants of Saturn! During its more than fourteen years of summer, the night must be enlivened by the bright reflection of this brilliant arch extending its luminous curve from the eastern to the western horizon; while even during the day, the sun must be materially aided by it in shedding light upon the world to which it belongs. 'There is no planet in the solar system,' says a late writer, 'whose firmament will present such a variety of splendid and magnificent objects as that of Saturn. The various aspects of his seven moons, one rising above

the horizon while another is setting; a third approaching the meridian; one entering into an eclipse, and another emerging from it; one appearing as a crescent, and another with a gibbous phase; and sometimes the whole of them shining together in one bright assembly: the majestic motions of the rings, at one time illuminating the sky with their splendour, and eclipsing the stars; at another, casting a deep shade over certain portions of the planet, and unveiling to view the wonders of the starry firmament—are scenes worthy of the majesty of the Divine Being to unfold, and the rational creature to contemplate.' Of the other planets it is unnecessary individually to speak; our knowledge of them is extremely limited, and we may simply remark, that in most of them the same causes exist which in our globe produce the various seasons. To the causes of the seasons, further than that they are the result of the influences of the celestial bodies, we will not here allude. To the arrangement of these, and to the forethought and all-pervading knowledge and goodness of Him who designed them, are we, in a word, indebted for the opening beauties of spring—the full glow of summer, arrayed in flowers and clothed with verdure—the sober and sear leaves of autumn, with its aureate fields and happy harvests—and the cold, but not desolate winter, which even in its fridity serves a valuable purpose in the scheme of the natural world. In these arrangements we see proofs of the care, the power, and the beneficence of that great Being who was the cause of all things. To what else, indeed, shall we trace the primary fact, that of all the heavenly bodies connected with our system, the sun alone, situated as he is in the centre, possesses undivided light, while the planets which surround him are all dark bodies receiving their light from him? There is no reason, in the nature of things, why a body placed in the centre of a system should give forth light and heat, while those revolving round it should be destitute of them. Yet we find it to be so: and we perceive the consequence of this arrangement to be not only most beneficial, but absolutely indispensable to the existence of the organised beings with which these orbs may be clothed or peopled.

But there is another view of the system of worlds to which our earth belongs, that strongly corroborates the existence of a creating and presiding Being. We mean the provision which is made for its perpetuity, notwithstanding the existence of so many conflicting forces—any one of which, if the system were differently arranged to what we find it to be, might in the course of ages derange the relations which the different bodies composing it possess towards each other, and precipitate the whole into confusion, only equalled by that chaos from which, by might and power, it was called. It will hardly be necessary minutely to explain the causes by which the earth and the other planets are kept in a continual state of rotation round the sun; but as perspicuity is one of the chief objects at which we aim, a few words on this subject will not be out of place. Let it be understood, then, that in every body of matter there exists a certain tendency to rush towards every other body, and that the larger, and denser, and nearer, any two bodies are, the greater is that tendency, and it will easily be comprehended that the sun, the largest of all the bodies in our system, should attract every other orb with a degree of force regulated by the size, the density, and the distance of each; so that, had all these bodies at first been placed in a state of rest in the universe, they would immediately have begun to move towards the sun, and thus in the course of time would, one after the other, have reached and been amalgamated with him in the form of one vast and irregular mass. But at the creation, this result was prevented by communicating to the planets an impulse at right angles to the diameter of their orbits, which, combining with the force of attraction—that is, the power of the sun in drawing or attracting the planets towards himself—caused the planets to revolve round the sun. If each of the planets, however, were to revolve round the sun, with no other prevailing power to interfere

with their motions except these two—namely, the attraction of the sun, and the original impulse at creation, they would of course continue as they are throughout all ages; but this is not the case. In the words of Mr Whewell, 'each of them is acted on by all the rest. The earth is constantly drawn by Venus, by Mars, by Jupiter, bodies of various magnitudes, perpetually changing their distances and positions with respect to the earth. The earth, in return, is perpetually drawing these bodies. What in the course of time will be the result? The cause acts perpetually, and it has the whole extent of time to work in. Is it not, then, easily conceivable that, in the lapse of ages, the derangements of the planets may accumulate, their orbits may change their form, their mutual distances may be much increased or much diminished? Is it not possible that these changes may go on without limit, and end in the complete subversion and ruin of the system?' What might have been the case had the balance of power, so to speak, in our system been differently disposed, it is not easy to say; but that all which is here suggested as possible would actually take place were a capricious or ignorant hand to interfere in the distribution of these forces, may assuredly be affirmed. We should soon have 'years of unequal length, and seasons of capricious temperature; planets and moons of portentous size and aspect, glaring and disappearing at uncertain intervals; tides like deluges sweeping over whole continents; and perhaps the collision of two planets, and the consequent destruction of all organisation in them both.' As the solar system exists, however, so nicely is it adjusted, that the deep inquiries of several of the philosophers of the last and current century, founded on the most complicated calculations, have shown that its arrangements are stable—that although there are, and may be perturbations, there are invariably proportionate compensations; so that whenever a maximum has been reached in the derangements of the system, it must necessarily begin to revert to its ancient order, and the restoration must in the end be as complete as was the derangement. It would require a hardihood greater than we can easily conceive to exist in the human mind, to view this subject, and to deny, after all, that a perfectly wise, beneficent, and powerful Being originally made, and has since sustained and governed all things.

It is proper, before leaving the heavenly bodies, to advert to the fixed stars. If little be known respecting the planets, still less has been ascertained regarding these more distant bodies; but it is by no means an unedifying employment to contemplate through them the immensity of creation, and thus elevated, to draw the conclusion that the Being by whom they originated must indeed be infinitely glorious. Had there been no other design on His part than thus to strike the mind of man with a sense of His magnificence and grandeur, no surer method could have been adopted to impart the lesson. The mind is bewildered when it dwells upon the glories which astronomy develops; and it cannot find words lofty enough to express its sense of the intelligence it discovers, or the proofs of the power, and wisdom, and goodness it perceives.

RELATIONS BETWEEN MAN AND EXTERNAL NATURE.

Leaving the evidences of design that are to be deduced from the contemplation of the heavens, let us regard some of the relations that exist between man and external nature, and consider the wonderful adaptations to each other which they exhibit. There can be no blank in nature, and consequently no body is isolated; all more or less influence each other, and it is of some of these relative influences that we are about to speak. Man is attached by the laws of gravitation to the earth which he inhabits, and is surrounded by an atmospheric medium capable of exercising certain influences upon him; these influences are modified to be subservient to his wants, and designed to be adapted not only to his necessities, but to those of every living thing, whether plant or animal, that exists. The air

which surrounds us exercises, in consequence of its extent, a pressure on the human body equal to about 31,536 pounds. But why do we not sink and miserably perish beneath this immense weight? It is by the reaction of the elastic fluids contained within our bodies that we are enabled to support so enormous a pressure. Here we find a mutual relation between us and the air, which cannot be interrupted without mutual injury. Suppose this weight to be withdrawn from our bodies, what would be the result? The expansibility of the fluids contained within us would have no restraint; they would dilate, burst through the solids which contain them, and destroy the individual. Place any animal beneath the receiver of an air-pump, and withdraw the air, the result is very apparent. We feel more or less the effects of any sudden change of atmospheric pressure, but still the density of the air is well adapted to the wants of man: had it been greater, our energies would have been oppressed, as by an unnatural load; and if less, insufficiently sustained, as by a defective support. The senses of hearing and smelling, too, which depend for their protection on a medium density of the air, would have been either insupportably intense or defective. Again, the atmospheric pressure materially affects temperature. If a certain quantity of air contains a certain quantity of heat, it is clear that it must be equally diffused throughout it; and if the same air be contained in less bulk, or if the pressure be greater, the heat is increased in the same ratio. In the same manner, if the pressure be lessened, the air expands, and with it the heat is diffused over a greater surface. By compressing air, we can produce a sufficient concentration of heat to cause ignition. This influence of the air upon the body is as universal as the former, and the adaptation of the one to the other as constant. With the exception of some countries near the equator, and there only in the hot season and the middle of the day, the temperature of the atmosphere is always below that of man; and as heat always tends towards an equilibrium, it is obvious that a constant subtraction of heat from the body must be going on. Now we are so organised as to allow of this universal subtraction; and indeed, were it suddenly stopped, or even diminished, we should soon perish. Again, if the subtraction became increased, or went on more rapidly than the vital principle could replace it, our temperature would sink, our humours and fluids freeze; and in this case, too, we should soon perish. But there are intermediate points between these two extremes; and as we before said, our organisation is such that it adapts itself to the degree. All organic bodies are capable of resisting to a great extent, and of modifying the action of, heat and cold; indeed, this principle of self-preservation is in them so striking as to have been regarded from a very early period as the most essential attribute of life. The power possessed by the higher classes of animals, of preserving a more or less uniform degree of heat, is almost unlimited. In very cold climates the thermometer not unfrequently sinks to 50° or 55° below the freezing-point; while in very hot ones it is sometimes 120° or 125° above it, making a difference of 170° or 180°; still, however, the temperature of the body remains unchanged. What unanswerable evidence of design is this, and how limitless must be that Power who could create such wonderful adaptations!

If the atmospheric pressure produces in some measure the regulation of heat and cold, in no less degree does it affect moisture and its concomitants—clouds, mist, rain, snow, and hail; and thus we are dependent for many of our comforts, and for most of our necessities, upon the due adjustment of atmospheric influences. Winds, too, arise from any unwonted atmospheric pressure disturbing the equilibrium of the atmosphere, and are the efforts of nature to restore the balance. All the changes of weather, the most violent storms and tempests, are owing to the same cause.

Connected with this subject, as evidencing design, is the composition of the air, which is precisely that best adapted to support respiration. It consists, besides

small proportions of aqueous vapour and carbon, of two fluids or gases called oxygen and nitrogen. In a separate state these gases are inimical to life. Lavoisier proved by experiment that pure air, or oxygen gas, if respired for a certain time, rarefies the blood too much, and increases the rapidity of the circulation, the effects of which are violent fever, inflammation of the lungs, and death. Nitrogen is equally destructive to life, as not yielding that principle on which the purification of the blood depends. It is their combination that renders them salutary to the constitution; neither consuming life by too much stimulus and excitement, nor deadening its energies by a languid circulation and depression of spirits. Why should the air have been composed exactly of twenty-one parts of oxygen and seventy-nine of nitrogen? Why were all other proportions excluded? It could not have been owing to a blind and fortuitous chance. The fact that we find two deadly ingredients so united as to become not only harmless, but salutary, must strike every mind with an unanswerable evidence of design. Atmospheric air is absolutely necessary both to animal and vegetable life, and both classes of beings are fully adapted for its reception. The boldest Epicurean could scarcely imagine that so necessary a substance has by mere chance surrounded this globe for the support of its inhabitants, upon whom, without it, God would have bestowed his power, and wisdom, and goodness in vain; nay, even had men, according to the doctrine of Epicurus, sprung up like mushrooms from the earth without an atmosphere, they could not have existed upon it. Has not, then, the hand of a wise Creator been here visibly employed, or why were we supplied with instruments that render the air available to us!—enabling us to resist its dreadful pressure, and to avail ourselves of its unutterable advantages. If we contemplate for a moment the evils which would have followed had not Divine intelligence presided at the constitution of our globe, and placed an atmosphere around it, how fearful and dreary it would have been! The moon has no atmosphere, and hence its climate must be very extraordinary; either the fiercest sunshine must reign, or the keenest frosts endure. If our earth had been similarly situated, no organic being would have adorned its surface; neither plant nor animal could have existed; no reflection of light could have taken place; no dawn or twilight would have prepared us for morning or for night; a dome blacker than darkness would have surrounded the earth, and light only have become manifest when the eye received it directly from the sun. The blue sky which now surrounds us, and which is owing to the thin watery vapours floating in the atmosphere, and reflecting peculiar rays of light, the blue and the violet, would not have been there. And where can we find such evidences of design as the blue colour which the sky exhibits? Of all hues we could imagine, is there any to surpass that mild and soft ethereal tint, harmonising with all around us, and on which the eye, fatigued with more brilliant and dazzling objects, turns for relief and repose? The unbeliever may say that this colour was the result of chance; but suppose any other, a bright yellow, a dazzling white, a glaring red, a fearful colour, how uncomfortable and painful would it have been for the vision of man! Again, an atmosphere is necessary to hearing; it enlarges the field of vision, and contributes also to the means of smell; and not only do the beings on earth enjoy life through its means, but it contributes to the sustenance of the finny tribes, enabling them not only to exist, but to rest in the water, or ascend and descend in it in quest of food.

There are still other relations existing between man and external nature, to which we would shortly allude, as illustrative of design; and they are such, that without them certain important functions could not be performed, and consequently man could not exist. These relations, which may be termed *organic*, are the more numerous and necessary to life, as the organisation of the individual is the more developed or complete; and while they may be all included in the two functions of

nutrition and sensation, they are the more multiplied as the operations of the former are more complex, and the extension of the latter greater; and hence they are more numerous in man than in any other animal. As in the physical relations, to some of which we have already alluded, so in the organic we must assign the first rank to the atmosphere, so necessary to life, and so admirably adapted to sustain it. It is the medium, also, through which we receive heat, light, and electricity, of which we appear to be as much in need as of that principle of air which purifies our blood, and fits it for the performance of its several operations. These matters are inherent in all living bodies; and if simple elementary bodies do exist, these are they. Many physiologists recognise the greatest analogy between the nervous fluid and electricity, and there is great reason for believing that it assists considerably in the maintenance of the vital phenomena. We know, however, that all these agents exercise a great influence upon life, from the demand that living bodies make upon them. Observe how plants languish and become weak when deprived of light, and how solicitously they move in the direction that will the most expose them to its invigorating influence. Nor is it less necessary to animal existence. But let us suppose that this element was only given for the purpose of enlightening the earth, what a wonderful relation, then, does it bear to the eye which perceives it! No one who considers the eye attentively can resist the impression of the evidence of design and skill which its construction exhibits. At the same time, it must be obvious that this construction of the eye would not answer its purposes unless the constitution of light corresponded to it. Light is an element of the most peculiar kind and properties, and such an element can hardly be conceived to have been placed in the universe without some regard to its operations and functions. As the eye is made for light, so light must have been made, at least among other ends, for the eye. What we have said of light is equally applicable to heat. It is obvious that the vital energy of plants is much diminished, even suspended, during winter, while with the return of summer they again shoot forth their leaves and flowers; the same alternation obtains also among hibernating animals. Heat is evidently the cause of these changes; so much so, indeed, that vegetables may be forced by artificial modes to invert the order of the seasons. The climates in fact demonstrate the influence of heat.

Electricity undoubtedly exists in the atmosphere in all its states; but we know very imperfectly the laws of this subtle agent, and are still more ignorant of its atmospheric operation. The present state of science, while it permits us to hazard an opinion, does not enable us to perceive those adaptations of its laws to its uses, which we can discover in those cases where the laws and the uses are both of them more apparent. 'It is at any rate very probable,' says Professor Whewell, 'that electricity has its important purposes in the economy of the atmosphere. And this being so, we may see a use in the thunderstorm and the stroke of the lightning. These violent events are, with regard to the electricity of the atmosphere, what winds are with regard to heat and moisture. They restore the equilibrium where it has been disturbed, and carry the fluid from places where it is superfluous, to others where it is deficient. We are so constituted, however, that these crises impress every one with a feeling of awe. The deep lowering of the gloom of the thundercloud, the overwhelming burst of the explosion, the flash from which the steadiest eye shrinks, and the irresistible arrow of the lightning, which no earthly substance can withstand, speak of something fearful, even independently of the personal danger which they may whisper. They convey, far more than any other appearance does, the idea of a superior and mightier Power, manifesting displeasure, and threatening punishment. Yet we find that this is not the language which they speak to the physical inquirer; he sees these formidable symptoms only as the means or the consequences

## NATURAL THEOLOGY.

of good. What office the thunderbolt and the whirlwind may have in the *moral* world, we cannot here discuss; but certainly *he* must speculate as far beyond the limits of philosophy as of piety, who pretends to have learned that these work more of evil than of good. In the *natural* world, these apparently destructive agents are, like all other movements and appearances of the atmosphere, parts of a great scheme, of which every discoverable purpose is marked with beneficence as well as with wisdom.

### DESIGN IN THE STRUCTURE OF THE EARTH.

It is evident, even on a very casual inspection, that the surface or crust of the globe we inhabit has undergone many changes, and these both great in extent and of long duration. Two agents, fire and water, have been mainly instrumental in their production. The ocean, the great source of aqueous influence, seems, from time immemorial, to have been engaged in a struggle to degrade or level the surface of the earth, not only by the direct action of its tides and currents upon coasts, but also by means of the clouds of vapour which it sends up into the atmosphere, and which re-descend on the earth in the shape of rain and snow, giving rise to numberless springs and rivers, all of which have some effect, less or more, in washing down the dry land. This system of detrition, carried on from age to age, would have produced a state of things very different from that which now exists, had it not been for the antagonising agency of fire, which, working from the centre outwards, either by extensive convulsions or by slow upheavements, has elevated and repaired the earth's surface as fast as the waters have abraded it, and has compelled the ocean to give back to the light, in the form of continents and islands, the materials which it had before swallowed up.

In this reciprocal action and counteraction, and in their effects upon the earth's surface, we find abundant proofs of benevolent design. By these means have been produced those extensive irregularities—that diversity of hill and vale, ridge and plain—on which depends the fitness of the earth for the maintenance of all organic life, whether animal or vegetable. If the surface were level and smooth, the vapours raised from the sea by the sun would find no channel for their return, and the globe would necessarily become a stagnant marsh, unsuited for the residence of man, and the greater part of the creatures that now tenant it along with him. But even if man could have inhabited the earth without its existing irregularities, how few comparatively would have been the advantages of his position! Had the matters carried down and deposited in the early seas, in the form of chalk-beds, limestone-beds, and coal-beds, with all the treasures of minerals and metals accompanying them, remained where they were first accumulated, man would have lost all the most essential elements of industry and civilisation. The changes and disruptions which have taken place in the crust, have brought to light a fund of riches, without which he would have been poor in comforts and in arts. Looking to those vast coal-fields alone which the crust of our globe contains, can we imagine for a moment that the great changes by which these ruined forests of the primeval world were first spread out and moulded into new forms, and then upheaved to the reach of man, to supply him with endless stores of heat, light, and wealth, were produced by blind chance, or by aught but a creative Designer, a being equally great and good?

On examining further into the condition of the earth's crust, as established by the changes it has undergone, we find numerous other proofs of the wise foresight which has ordered and arranged the whole. We discover that all the successive mutations of our planet, extensive as they have evidently been, were rendered compatible with the existence and enjoyment of countless numbers of organised and sentient beings. All the rocky strata of the crust, with the exception of those which appear to be the oldest and deepest-seated, are mixed up abundantly with organic remains, both animal

and vegetable. In short, whatever was the state of the surface at any given period of the revolutions progressively fitting it for the ultimate residence of man, we find organised beings to have sprung up upon it, with such habits and peculiarities of structure as enabled them to exist and enjoy existence under the peculiar circumstances in which they were placed.

### DESIGN IN ANIMAL PHYSIOLOGY.

The earth, whose structure we have just briefly noticed, serves as the place of habitation for two kinds of existences—the animal and vegetable—in whose formation and functions we discover the beautiful dispensations of Providence, extending on every side over a vast range of beings, and demonstrating the unity of plan on which organised creation has been devised. And first, the whole circle of our knowledge does not afford greater evidence of design than comparative anatomy: in it we find innumerable contrivances for the comfort and happiness of the different tribes of beings adapted to the peculiarities of their condition; in each animal we see the same organ repeated, but modified to render it more available to the habits of its possessor; and among all the wonders of creation, there are none which strike the inquiring mind more forcibly than this change or modification of formation for the obvious purpose of accommodation to circumstances. Were all animals formed alike, or did the differences which exist between them bear no relation to their habits or destinies, it would be less easy to refute the doctrine which assigns all things to material causes, and excludes the designing hand of an intelligent Creator. Although even then the argument would be totally untenable, still, the demonstration which disproves it would have been less satisfactory and perfect, as the surprising skill and beneficent care by which the structure of every animal is adapted to its individual habits and necessities could not have been so well displayed. A single tool in the hands of the carpenter is a proof of contrivance; but that proof is much multiplied, and rendered more forcible, when we find the same instrument modified into a thousand forms to suit the different operations of the workman. Few of the functions of animated beings better illustrate this than that of alimentation, which we shall now endeavour briefly to trace, through the humble zoophytes and worms up to birds and mammiferous animals.

#### Structure of Zoophytes, &c.

Nutrition is common to all animals without exception; and the numerous and varied modifications of the means employed to effect it, are obvious proofs of the design and intelligence of the Creator. There are some animals so nearly allied to plants as to be scarcely distinguishable from them; and in these, as in plants, nutritive matter is introduced by mere imbibition. Fixed like plants to the spot where they grow, any other organs would have been superfluous; while to those which are not so attached, but seek their food and obtain it through their locomotive powers, organs for seizing and preparing it are necessary. In them, therefore, we find lips variously and curiously modified; glands about the mouth for furnishing fluids for lubricating dry alimentary matters; a tongue, or something analogous to it; teeth and jaws for breaking down hard substances, and rendering them fit for swallowing; with a passage called the *oesophagus*, or gullet, leading from the mouth to the stomach, in which the food is at last assimilated, and rendered fit for nourishing the animal. But it is not until we advance some way in the great chain of animal life that these parts become sufficiently obvious, or their offices clearly defined. In the very lowest orders, the mouth and stomach are one continuous tube, or all stomach, as it may be called, and so simple in construction, that the animal may be turned inside out without detriment to it; that which was external being now internal, and performing, apparently with equal facility, all the offices of what was previously the stomach. As we advance, however, we

find the nutritive organs ceasing to be a mere sucking apparatus, or a receptacle for imbibed fluids. In those wheels which are furnished with proboscides, we find a cavity occupied by the aperture of the œsophagus, a tongue, and teeth; while the snail possesses a perfectly-formed mouth and lips. Among the worms, whose stomachs are generally membranous bags, we find examples of wonderful contrivance and design. Thus the powerful stomach of one species contains three hard calcareous shells, by which the individual is enabled to bruise and masticate the shelled animals on which it feeds. The discoveries of Ehrenberg respecting the animalculæ inhabiting different vegetable infusions, have extended in an extraordinary degree our knowledge of the stupendous power of God; and the inimitable proofs of design displayed in beings to whom, in relative size, the mite is as an elephant, afford astonishing displays of a minute and most beneficent attention to the preservation of these curious creatures, in whose organisation and instincts new and admirable indications of creative wisdom are revealed. By the aid of the microscope, we are enabled to perceive the Creator of the universe minutely busy among the worlds of living creatures to which he has given birth on a blade of grass, or in a drop of water, and to discover fresh scenes of wonder, and interest, and evident design among hosts of animated beings, infinite in number as they are in minuteness.

As we ascend higher in the scale of existence, we find the digestive apparatus ceasing to be simple cavities, or canals hollowed out of the substance of the body, and becoming distinct organs formed by membranes and coats proper to each; and among these, the first example occurs in the sea-anemone, in which we find spaces intervening between the coats of the stomach and the skin of the animal: here, however, the stomach is still a blind pouch, one aperture serving alike for receiving and ejecting the alimentary matters. In the *echini*, or sea-urchin, these organs are still more perfect. Those of mastication are peculiarly developed; an œsophagus, or gullet, also presents itself, and a stomach continued into a regular intestine, which takes two turns in the body before it terminates.

#### Structure of Insects.

In the digestive organs of insects we meet with a multitude of new and peculiar formations, while most of the simple forms found in the lower animals are here repeated. The organs of mastication, deglutition, and suction, present such remarkable differences, that the arrangements of modern systems of entomology have been chiefly founded on them. In this order of animals, nutrition by vegetable substances is much more common than in those below it; indeed, as Blumenbach has observed, the business of nutrition in insects does not seem to have for its object the mere preservation of the individual, as in most red-blooded animals, but chiefly the consumption of organised matter, which will appear from considering the structure of their alimentary canal. In most of those which are subject to a metamorphosis, the stomach in the larvæ state is of a great size in comparison with the short intestinal canal; while those, on the contrary, which take little or no nourishment in their perfect state, have this organ remarkably diminished, and, as it were, contracted. How beautifully does the great size and straight course of the intestinal apparatus of the animal, when in its caterpillar state, coincide with its enormous voracity and quick digestion! It has been computed that caterpillars sometimes devour and digest no less than three times their own weight of aliment in four-and-twenty hours. On the other hand, during the subsequent metamorphosis which the animal undergoes, no food is taken; but nature, or rather the God of nature, has wonderfully, and with beneficent design, provided against any necessity for this, by causing insects to become very fat, as observed by Malpighi, on the approach of these changes; so that this fat, being absorbed into the blood while these are going on, serves all the purposes of a supply

of alimentary matters from without. The insects now under consideration exhibit at different periods of their existence the greatest contrasts, not only in external form, but also in their habits, instincts, and modes of subsistence. The larvæ, as we have seen, is remarkable for its voracity, requiring large supplies of food, and consuming enormous quantities of vegetable matter; the perfect insect or butterfly, having attained its full dimensions, is sufficiently supported by small quantities of a more nutritious food, consisting either of animal juices or of the fluids prepared by flowers, which are generally of a saccharine quality, and contain nourishment in a highly-concentrated form. It is evident that the same apparatus which is necessary for the digestion of the bulky food taken in during the former period, would not be suited for the assimilation of that which is received during the latter; and that in order to accommodate it to this altered condition of its function, considerable changes must be made in its structure. Who can believe that these changes are made without wisdom, or persuade themselves that all this is to be brought about by causes divested of knowledge and understanding? Dr Roget, in his admirable *Bridge-water Treatise*, has beautifully illustrated the subject, by very clear and correct drawings by Mr Newport, of the three different states of the entire alimentary canal of the privet hawkmoth (*Sphinx ligustri*): first when a caterpillar; then as a chrysalis; and lastly as the moth: and of these, taking our text from Roget, or rather from Herold, we shall endeavour to give some account. We have seen that in the caterpillar the stomach forms by far the most considerable portion of the alimentary canal, bearing some resemblance in its structure and capacity to the stomachs of certain worms. This is followed by a large, but short and perfectly straight intestine. In the chrysalis, these organs have undergone considerable modifications; the whole canal, but more especially the stomach, being contracted both in length and width: the shortening of the intestine not being proportionate to that of the whole body, obliges it to be folded upon itself for a certain length. In the moth, the contraction of the stomach has proceeded much farther, and an additional cavity, which may be considered as a kind of craw, is developed; the small intestine takes a great many turns during its course, and a large pouch has been formed at the part where it joins the large intestine. 'When we consider,' say Kirby and Spence, speaking of the phenomena which we have detailed, 'the adaptation of all these changes of form, the loss of old organs and the acquisition of new ones, to the functions and mode of life of the animal, we see evidently the all-powerful hand of that Almighty Being who erected the universe, upholding by his providence, and the law that he has given to every creature, the system that he at first brought into existence.'

In insects, all parts concerned in digestion are in general smaller and less complicated in the carnivorous than in the herbivorous tribes, apparently from the matters on which the former subsist being already animalised, and requiring therefore less preparation before they are received into the blood; and it is no slight indication of design to observe in them how admirably parts are adapted to the animal necessities. Thus scorpions, spiders, millepedes, and others which live for the most part on hard animal substances, are furnished with jaws of a firm horny texture, in many cases very large, when compared with the size of the animal; dragon-flies and beetles, particularly the stag-beetle, are examples in which the jaws are very large and manifest, often possessing tooth-like edges; and these, too, feed on smaller insects than themselves. In another description, of which the bee, wasp, and ant are examples, we find the animal deserting the coarser kinds of food, living chiefly on juices; and in them also we again find the same mode of taking in nourishment as in the lowest stages of the animal kingdom—namely, by means of organs of suction, which here, however, are combined with organs for mastication. These organs

of suction are still more developed in insects, such as gnats, house-flies, &c.; in them they consist of a tube, of which the sides are strong and fleshy, and movable in every direction, like the trunk of an elephant, and having at its extremity a double fold, resembling lips, which are well adapted for suction. The gnat, and other insects which pierce the skin of animals, have for this purpose instruments termed *lancets*, from their shape and office. In the gnat they are five or six in number, finer than a hair, exceedingly sharp, and generally barbed on one side; while in the house-fly they are flat, like the blade of a knife. In the butterflies, however, which are almost wholly independent of solid nutritive matter, these organs present themselves in the greatest perfection, and without any addition of teeth. The proboscis of this order of insects is a double tube, constructed by the two edges being rolled longitudinally till they meet in the middle of the lower surface, thus forming a tube on each side, but leaving also another tube, intermediate to the two lateral ones. This middle tube is formed by the junction of two grooves, which, by the aid of a curious apparatus of hooks, lock into each other, and can be either united into an air-tight canal, or be instantly separated at the pleasure of the animal. It would be quite incompatible with the nature of this essay to enter at greater length into the evidences of design deducible from the digestive apparatus of insects: no one can be blind enough to deny that it evinces an origin of things quite incompatible with mere brute and uncertain chance.

#### Structure of Fishes and Reptiles.

Still ascending in the scale of creation, we come to the contemplation of fishes. We ask, was it by mere chance that the respiratory apparatus of fishes was so formed that their blood receives its vivifying principle from the air which is held in solution by the water in which they move? And who cannot, in this one instance, but discern the hand of a ruling Providence, adapting the structure of animals to the habits which are to characterise them? Was it by chance that in the plaice, the sole, the turbot, and other flat fishes, the eyes are placed both on one side of the body, an isolated instance of a want of uniformity in the two sides? No: the design is obvious; for as these animals are destined to continue always with one side in the mud at the bottom of the water, an eye on this side would have been superfluous and inconvenient to them. The same design and evident adaptation of structure to circumstances is apparent in the Surinam sprat. This singular animal generally swims so near the surface, that its eye is partly in and partly out of the water; and all its parts correspond with this strange peculiarity, the pupil being partially divided into an upper and a lower portion, and the lens consisting of two globes, an upper and a lower one attached together. It appears that the superior part of the eye is, like that of terrestrial animals, adapted to refract rays transmitted by air, and the inferior part, like that of aquatic animals, those transmitted by water, and that the refracting power of the several parts of the eye is accordingly much less above than below. With regard to the function of hearing, we find in fishes the Creator still proceeding on one vast plan or unity of design; with the exception of one species, all the parts of the ear are buried within the skull, and send no process to the surface; and this is precisely what we should have looked for in beings destined to hear through the medium of water, the vibrations of which being so much more powerful than those of air, would render the complicated apparatus requisite in terrestrial animals in them superfluous. In the class of fishes, we see the lowest condition of the alimentary canal as it is found in vertebral animals. Fishes, voracious to a proverb, subsist almost entirely on animal food. The ocean teems chiefly with animal life. It is a dense, and rich, and moving, and temperate element, where vegetation is comparatively small, contrasted with its development in the light and unresisting element of the atmosphere. This rich and

resisting element of water abounds in every latitude and in every drop, with all forms of animated beings. Thus fishes have the means of easily satisfying their voracious appetites with a selection of all kinds of food. Their teeth, more instruments of prehension than mastication, are sharp, recurved, dense, and pointed cones, adapted to grasp and retain every living thing that moves in the waters, and placed in all parts of the mouth of these all-devouring animals; their oesophagus, or gullet, is very wide and short, and directly opening into their capacious stomach. Thus the food of fishes not being masticated in the mouth, does not dwell there; and as they are surrounded with an abundance of moisture, they require no salivary glands for lubricating the food, and they have none. Like larvæ, their stomachs are very large; and like them also they are chiefly intent upon the gratification of their appetites. The intestine of fishes varies considerably in length, according to the kind of food; but, generally speaking, it is not longer than their bodies; whereas in most reptiles—which compose the next class of animals in the ascending scale—it is considerably longer; a provision unnecessary in fishes, perhaps from the matters on which they for the most part feed being almost always of the same nature as their own bodies, and therefore requiring comparatively little preparation.

Relinquishing our plan of illustrating design by an account of the digestive apparatus, let us consider, in reptiles, the organs subservient to the function of respiration, which, though somewhat similar to the organs designed for that purpose in birds and mammiferous quadrupeds, differ from those in some remarkable particulars. In reptiles, indeed, as in birds and mammals, there is a kind of lungs; but they are membranous, and not fleshy—that is to say, the cells which they contain are so much larger as to give them a membranous, and not a fleshy appearance—nay, in many reptiles the lungs consist of one membranous bag, very similar to the air-bladder of fishes. These lungs or bags are situated in the abdomen, and are loose and floating among the entrails; and they receive their supply of air, in general, not as in birds and mammiferous animals, in consequence of the formation of a vacuum around them, but by a process very similar to that of swallowing. Hence reptiles, unlike the higher classes of animals, can still continue to breathe if their bodies are cut open, because they do not require a vacuum round the lungs. The air thus received is subservient to the purification of the blood in the usual manner; but it is not so immediately vitiated as air received into fleshy lungs, owing to the larger size of the cells, which do not immediately allow the whole of it to come into contact with their sides. This is one reason why reptiles can sustain an impediment to their respiration for a much longer time than birds and mammals; but another and a much better reason is to be found in the distribution of their blood-vessels; those going to the lungs not forming a necessary part of the general circulating system, but constituting, as it were, only an appendage to it, which may for a time cease to transmit blood without inconvenience.

#### Structure of Birds.

We come now to birds; and whether we consider their external form or anatomical structure, or in whatever light it is possible to view them, the same conclusion presents itself to the mind. Inexhaustible contrivance, vast and comprehensive intelligence, are everywhere conspicuous. Behold in their pointed bill, and gradually enlarging head and neck, a means of penetrating the yielding air; then the prow-like breast, the flexible rudder tail, the equipoised wings, and feathers at once adapted for lightness, for strength, and for tenacity, and all bearing relations, not only to each other, but to the air in which the animal is to fly: the wise contrivance of these could not be the result of chance. The investing membranes of their lungs, prolonged from various parts of their surface in the form of tubes, and expanding into bags, enveloping almost

all the entrails, so as to keep them constantly surrounded with air, and similar prolongations extending also into the cavity of their bones, serving to inflate these in the same manner—are not these peculiarities for the obvious purpose of giving lightness to the animal, and thus enabling it to support itself in the air!—and does not this palpable subserviency of one part of the structure of birds to the rest, irresistibly inculcate the truth that one master-hand has regulated the whole!

In the beaks or bills of birds, various as are their forms, we can trace an exact adaptation to the food of the species. In those that tear their prey, as the eagle and hawk—or bruise hard fruits, as the parrot—or penetrate the bark of trees, as the woodpecker—the bills are of extraordinary hardness, and, in form, intimately connected with the habits of the animal. In those to whom a sense of feeling in this part is necessary to enable them to find their food in mud or water, as the duck, it is very soft, generally flattened, and so constructed that fluids may filter through it, while the solid food is retained. A bill hooked at the end, with sharp edges, characterises birds of prey. Another species of strong sharp-edged bill, of an elongated shape, but without a hook, serves to cut and break, but not to tear; and this is the form of the bill in birds which live upon animals which make resistance in the water; some of these are straight, as in the heron—others curved, some downwards, some upwards. Some sharp-edged bills have their sides approximating, like the blade of a knife to its handle, and thus adapted to seize small substances; as the penguin. The small, conical, arched bill of poultry serves only to take up grain. The bills of the smaller birds present all the varieties of the conical form, from the broad-based cone of the hawfinch to the thread-like cone of the humming-bird. Such of them as have strong short bills live on grain; those with long thin ones, on insects. Where the bill is short, flat, opening very anteriorly, as in martens and swallows, the bird seizes flies and butterflies in the air; and if it be long and curved, possessing some strength, we find it grubs up worms for its food. The same evidence of design which we discover in the bills of birds adapting them to procure the kind of food on which the individual is to subsist, is apparent also in the conformation of their digestive organs. As the food of birds varies from the softest animal matter to the hardest grain, so we observe every gradation in the structure of their stomachs, from the membranous sac of the carnivorous tribes to the true muscular gizzard of granivorous birds—varying according as the food consists of animal or vegetable materials, or presents more or less resistance from the cohesion of its texture.

In no branch of natural history do we find more remarkable evidences of design than in the varieties of kinds of covering of animals adapted to their wants and situations on the globe. The covering of birds, in particular, 'cannot,' says Paley, 'escape the most vulgar observation. Its lightness, its smoothness, its warmth—the disposition of the feathers all inclined backward, the down about their stem, the overlapping of their tips, their different configuration in different parts, not to mention the variety of their colours, constitute a vesture for the body so beautiful, and so appropriate to the life which the animal is to lead, as that, I think, we should have had no conception of anything equally perfect if we had never seen it, or can now imagine anything more so. Let us suppose (what is possible only in supposition) a person who had never seen a bird to be presented with a plucked pheasant, and bid to set his wits to work how to contrive for it a covering which shall unite the qualities of warmth, levity, and least resistance to the air, and the highest degree of each: giving it also as much of beauty and ornament as he could afford. He is the person to behold the work of the Deity, in this part of His creation, with the sentiments which are due to it.

The commendation which the general aspect of the feathered world seldom fails of exciting, will be increased by further examination. It is one of those

cases in which the philosopher has more to admire than the common observer. Every feather is a mechanical wonder. If we look at the quill, we find properties not easily brought together—strength and lightness. I know few things more remarkable than the strength and lightness of the very pen with which I am writing. If we cast our eye to the upper part of the stem, we see a material, made for the purpose, used in no other class of animals, and in no other part of birds; tough, light, pliant, and elastic. The pith, also, which feeds the feathers is, amongst animal substances, *sui generis*; neither bone, flesh, membrane, nor tendon.

But the artificial part of a feather is the beard, or, as it is sometimes, I believe, called, the vane. By the beards are meant what are fastened on each side of the stem, and what constitute the breadth of the feather; what we usually strip off from one side or both when we make a pen. The separate pieces, or laminae, of which the beard is composed are called threads, sometimes filaments or rays. Now the first thing which an attentive observer will remark is, how much stronger the beard of the feather shows itself to be, when pressed in a direction perpendicular to its plane, than when rubbed, either up or down, in the line of the stem; and he will soon discover the structure which occasions this difference—namely, that the laminae whereof these beards are composed are flat, and placed with their flat sides towards each other; by which means, whilst they *easily* bend for the approaching of each other, as any one may perceive by drawing his finger ever so lightly upwards, they are harder to bend out of their plane, which is the direction in which they have to encounter the impulse and pressure of the air, and in which their strength is wanted, and put to the trial.

This is one particularity in the structure of a feather: a second is still more extraordinary. Whoever examines a feather, cannot help taking notice that the threads, or laminae, of which we have been speaking, in their natural state *unite*; that their union is something more than the mere apposition of loose surfaces; that they are not parted asunder without some degree of force; that nevertheless there is no glutinous cohesion between them; that therefore, by some mechanical means or other, they catch or clasp among themselves, thereby giving to the beard, or vane, its closeness and compactness of texture. Nor is this all: when two laminae which have been separated by accident or force are brought together again, they immediately *reclasp*: the connection, whatever it was, is perfectly recovered, and the beard of the feather becomes as smooth and firm as if nothing had happened to it. Draw your finger down the feather, which is against the grain, and you break, probably, the junction of some of the contiguous threads; draw your finger up the feather, and you restore all things to their former state. This is no common contrivance: and now for the mechanism by which it is effected. The threads or laminae above-mentioned are *interlaced* with one another, and the interlacing is performed by means of a vast number of fibres, or teeth, which the laminae shoot forth on *each side*, and which hook and grapple together. A friend of mine counted fifty of these fibres in one-twentieth of an inch. These fibres are crooked, but curved after a different manner; for those which proceed from the thread on the side towards the extremity of the feather are longer, more flexible, and bent downwards; whereas those which proceed from the side towards the beginning or quill end of the feather, are shorter, firmer, and turn upwards. The process, then, which takes place is as follows:—When two laminae are pressed together, so that these long fibres are forced far enough over the short ones, *their* crooked parts fall into the cavity made by the crooked parts of the others, just as the latch that is fastened to a door enters into the cavity of the catch fixed to the door-post, and there hooking itself, *fastens* the door; for it is properly in this manner that one thread of a feather is fastened to the other.

This admirable structure of the feather, which, it is easy to see with the microscope, succeeds perfectly for

the use to which nature has designed it; which use was, not only that the laminae might be united, but that, when one thread or lamina has been separated from another by some external violence, it might be reclasped with sufficient facility and expedition.

In the *ostrich*, this apparatus of crotchets and fibres, of hooks and teeth, is wanting; and we see the consequence of the want. The filaments hang loose and separate from one another, forming only a kind of down; which constitution of the feathers, however it may fit them for the flowing honours of a lady's head-dress, may be reckoned an imperfection in the bird, inasmuch as wings composed of these feathers, although they may greatly assist it in running, do not serve for flight.

But under the present division of our subject, our business with feathers is, as they are the *covering* of the bird. And herein a singular circumstance occurs. In the small order of birds which winter with us, from a snipe downwards, let the external colour of the feathers be what it will, their Creator has universally given them a bed of *black* down next their bodies. Black, we know, is the warmest colour: and the purpose here is, to *keep in* the heat arising from the heart and circulation of the blood. It is further likewise remarkable, that this is not found in larger birds; for which there is also a reason:—Small birds are much more exposed to the cold than large ones; forasmuch as they present, in proportion to their bulk, a much larger surface to the air. If a turkey were divided into a number of wrens (supposing the shape of the turkey and the wren to be similar), the surface of all the wrens would exceed the surface of the turkey, in the proportion of the length and breadth (or of any homologous line) of a turkey to that of a wren; which would be perhaps a proportion of ten to one. It was necessary, therefore, that small birds should be more warmly clad than large ones; and this seems to be the expedient by which that exigency is provided for.

The oil with which birds prune their feathers, and the organ which supplies it, is a specific provision for the winged creation. On each side of the rump of birds is observed a small nipple, yielding upon pressure a butter-like substance, which the bird extracts by pinching the pap with its bill. With this oil or ointment thus procured, the bird dresses its coat, and repeats the action as often as its own sensations teach it that it is in any part wanted, or as the excretion may be sufficient for the expense. The gland, the pap, the nature and quality of the excreted substance, the manner of obtaining it from its lodgment in the body, the application of it when obtained, form, collectively, an evidence of intention which it is not easy to withstand. Nothing similar to it is found in unfeathered animals. What blind *wisdom* of nature should produce it in birds! should not produce it in beasts!

As we have entered so fully into this subject when treating of other classes of beings, we shall not here revert to it, or bring forward illustrations of the truth of our proposition; the facts already detailed seem sufficient to display the wisdom which the great Creator has evinced in this department of the animal world. Nothing can be more worthy of remark than the exhaustless contrivances by which every difficulty is obviated, and nature moulded to the will of its Almighty Author. How many obstacles were to be overcome before a heavy body like that of an eagle or the mighty condor could be rendered buoyant in the air, and made to track its adventurous course so high above the earth as to be almost lost to human gaze! How many conditions were necessary to give safety and enjoyment to the smallest of the winged tribes, even after the first obstacles were overcome! And yet how wonderfully simple and efficacious the mechanism by which the whole has been accomplished!

Structure of the Mammalia.

We now arrive at the consideration of the mammalia, or those animals which suckle their young; and at the head of this great class we find man proudly pre-emi-

nent. We have already seen that as the materials on which the function of digestion is to be performed are numerous and diversified, so a difference exists in the parts which are subservient to it. Without altering the general plan of the function, or the essential parts of the organs concerned in it, nature makes such additional provisions, in the instincts by which the reception of food is guided, and in the organs by which it is assimilated, as are suited to the circumstances in which the animal is placed, to the food on which it is to subsist, and to the ulterior purposes which it is to serve in the world. Such evidences of design are very remarkable in the mammalia; and in few organs are they more powerfully instanced than in the teeth, between which in form, structure, and position, and the kind of food on which each animal of this class is intended to subsist, the most intimate connections present themselves. These relations—which, indeed, may be also traced in the shape of the jaw, in the mode of its articulation with the head, in the proportional size and distribution of the muscles which move the jaw, in the form of the head itself, in the length of the neck and its position on the trunk, and, in fact, in the whole conformation of the skeleton—have been noticed from very early ages, and frequently described.

The purposes answered by the teeth are principally those of seizing and detaining whatever is introduced into the mouth, of cutting it asunder, and dividing it into smaller pieces, of loosening its fibrous structure, and of breaking down and grinding its harder portions. Four principal forms have been given to teeth, which accordingly may be distinguished into the conical, the sharp-edged, the flat, and the tuberculated teeth; though we occasionally find a few intermediate modifications of these forms. It is easy to infer the particular functions of each class of teeth, from the obvious mechanical actions to which, by their form, they are especially adapted. The conical teeth, which are generally also sharp-pointed, are principally employed in seizing, piercing, and holding objects; such are the offices they perform in the crocodile and similar reptiles, where all the teeth are of this structure; and such also are their uses in most of the cetacea or whale tribe, where similar forms and arrangements of teeth are found to prevail. The animals subsist on fish, and their teeth are therefore constructed very much on the model of those of fish; while those cetacea, on the other hand, which are herbivorous, as the manatus and dugong, have teeth very differently formed.

The sharp-edged teeth perform the office of cutting and dividing the yielding textures presented to them: they act individually as wedges or chisels; but when co-operating with similar teeth on the opposite jaw, they have the power of cutting like shears or scissors. The flat teeth, of which the surfaces are generally rough, are used, in conjunction with those meeting them in the opposite jaw, for grinding down the food by a lateral motion, in a manner analogous to the operation of millstones in a mill. The tuberculated teeth, of which the surfaces present a number of rounded eminences, corresponding to depressions in the teeth opposed to them in the other jaw, act more by their direct pressure in breaking down hard substances, and pounding them as they would be in a mortar.

The apparatus for giving motion to the jaws is likewise varied according to the particular movements required to act upon the food in the different tribes. The articulation of the lower jaw to the skull is somewhat similar to a hinge; but considerable latitude is given to its motions by the interposition of a movable cartilage between the two surfaces of articulation, a contrivance admirably answering the intended purpose. Hence, in addition to the principal movements of opening and shutting, which are made in a vertical direction, the lower jaw has also some degree of mobility in a horizontal or lateral direction, and is likewise capable of being moved backwards or forwards to a certain extent. In the conformation of the teeth and jaws, a remarkable contrast is presented between carnivorous and herbi-

vorous animals. In the former, of which the tiger may be taken as an example, the whole apparatus for mastication is calculated for the destruction of life, and for tearing and dividing the fleshy fibres. The teeth are armed with pointed eminences, which correspond in the opposite jaws, so as exactly to lock into one another, like wheelwork, when the mouth is closed, and the muscles which close it are of enormous size and strength. In the herbivorous animals, on the contrary, as in the antelope, the greatest force is bestowed, not so much on the motions of opening and shutting, as on those which are necessary for grinding, and which act in a lateral direction. The surfaces of the teeth are flattened, and of great extent; and they are at the same time kept rough, like those of millstones, their office being in fact very similar to that performed by these implements of grinding. The *Rodentia*, or gnawing quadrupeds, are formed for subsisting on dry and tough materials, such as the bark and roots, and even the woody fibres of trees, and the harder animal textures; and their teeth are expressly adapted for gnawing, nibbling, and wearing away, by continued attrition, the harder texture of organised bodies. They are all furnished with two front teeth, generally very long, and having the exact shape of a chisel; while the molar or back teeth have surfaces irregularly marked with raised zig-zag lines, rendering them very perfect instruments of trituration. The beaver and common rat are examples among omnivorous rodentia, and the hare and rabbit among those that are principally herbivorous.

The *Quadrumania*, or monkey tribes, approach nearer to the human structure in the conformation of their teeth, which are adapted to a mixed kind of food; while the other orders of mammalia exhibit gradations in the structure of their teeth corresponding to the varieties in the nature of their food. 'On comparing the structure of the digestive organs of man,' continues Dr Roget, 'with those of other animals belonging to the class mammalia, we find them holding a place in the series intermediate between those of the purely carnivorous and exclusively herbivorous tribes, and in some measure uniting the characters of both. The powers of the human stomach do not indeed extend to the digestion of either the tough woody fibres of vegetables on the one hand, or the compact texture of bones on the other; but still they are competent to extract nourishment from a wider range of alimentary substances than the digestive organs of almost any other animal. This adaptation to a greater variety of food may also be inferred from the form and disposition of the teeth, which combine those of different kinds more completely than in most mammalia. In addition to these peculiarities, we may also here observe, that the sense of taste in the human species appears to be affected by a greater variety of objects than in the other races of animals. All these are concurring indications that nature, in thus rendering man omnivorous, intended to qualify him for maintaining life wherever he could procure the materials of subsistence, whatever might be their nature, whether animal or vegetable, or a mixture of both, and in whatever soil or climate they may be produced; and for endowing him with the power of spreading his race, and extending his dominion over every accessible region of the globe. Thus, then, from the consideration of the peculiar structure of the organs of his frame, may be derived proofs of their being constructed with reference to faculties of a higher and more extensive range than those of any, even the most favoured, species of the brute creation.'

There is one circumstance connected with the function of digestion, as displayed in certain of the mammalia, to which, as evidencing great and wonderful design and accommodation in structure to circumstance, we would particularly allude: it is the facility and power of the camel of abstaining long from drinking—a power which he is often necessitated to bring into effect during the long period of nine, ten, or even twelve days. It is by the singular structure of the camel's stomach that it is enabled to pass such a time without drink-

ing, and to take in at once a prodigious quantity of water, which remains in reservoirs pure and limpid, because these wells are so contrived that neither the fluids of the body nor of digestion can mix with it. What design is here!—and how redolent of wisdom, and how full of mercy! But let us endeavour to explain the nature of this structure which so evidently adapts the camel to be the inhabitant of the sterile and arid regions of the East:—Ruminating quadrupeds, or those which chew the cud, have two, three, or four stomachs, distinguished, when there are four, by the names of *paunch*, *bonnet*, *many-plies*, and *caille*. When the food is swallowed for the first time, it passes directly from the gullet into the paunch, where it undergoes some necessary changes, and it is then transmitted to the bonnet, to be mixed with the fluids of the cavity. This process is going on during the time the animal is grazing, when, from the incessant occupation of nipping off the grass, for which its teeth are so admirably suited, it has not leisure to chew it sufficiently. When afterwards reposing itself, however, the half-chewed aliment is brought again in successive little balls, from the bonnet into the mouth, where it is subjected to a perfect mastication; and when again swallowed, it passes directly to the many-plies, thence, after some time, to the caille, and ultimately to the intestines. In the camel, however, the paunch has two deep cellular appendages; and the bonnet, or second stomach, has its internal membrane hollowed into numerous deep cells, serving as reservoirs of water, to be used only as occasion requires; while the third stomach is alone appropriated to the immediate necessities of the body. Between the end of the gullet, then, and the orifice of this third stomach, extends, through the two first, a long muscle capable of drawing up the third stomach, so as to receive alimentary matters directly from the gullet, when the immediate wants of the animal are to be supplied; but when the fluid taken is meant to be used only in its long journeys through the deserts, this muscle is relaxed, and it is thus received into the two first stomachs, and transmitted onwards by these only at the necessary intervals. The Arabs who traverse these extensive plains, accompanied by these useful animals, are, it is said, sometimes obliged, when faint, and in danger of perishing from thirst, to kill one of their camels, for the sake of the water contained in these reservoirs, which is always found pure and wholesome.

#### Compensation of Parts in Animated Nature.

The evidences of design in creation are beautifully developed in what is called the compensatory structure of animals. By this is signified the supplying the defects of one organ by the structure of another part or organ. Paley has summed up a few striking instances of this nature. 'The short unbending neck of the elephant,' says he, 'is compensated by the length and flexibility of his *proboscis*. He could not have reached the ground without it; or, if it be supposed that he might have fed upon the fruit, leaves, or branches of trees, how was he to drink! Should it be asked, Why is the elephant's neck so short! it may be answered, that the weight of a head so heavy could not have been supported at the end of a longer lever. To a form, therefore, in some respects necessary, but in some respects also inadequate to the occasions of the animal, a supplement is added, which exactly makes up the deficiency under which he laboured.

If it be suggested that this *proboscis* may have been produced, in a long course of generations, by the constant endeavour of the elephant to thrust out his nose (which is the general hypothesis by which it has lately been attempted to account for the forms of animated nature), I would ask, How was the animal to subsist in the meantime, during the process, *until* this prolongation of snout were completed! What was to become of the individual whilst the species was perfecting!

Our business at present is simply to point out the relation which this organ bears to the peculiar figure of the animal to which it belongs. And herein all things

correspond. The necessity of the elephant's proboscis arises from the shortness of his neck; the shortness of the neck is rendered necessary by the weight of the head. Were we to enter into an examination of the structure and anatomy of the proboscis itself, we should see in it one of the most curious of all examples of animal mechanism. The disposition of the ringlets and fibres, for the purpose, *first*, of forming a long cartilaginous pipe; *secondly*, of contracting and lengthening that pipe; *thirdly*, of turning it in every direction at the will of the animal; with the superaddition, at the end, of a fleshy production of about the length and thickness of a finger, and performing the office of a finger, so as to pick up a straw from the ground—these properties of the same organ taken together, exhibit a specimen not only of design (which is attested by the advantage), but of consummate art, and, as I may say, of elaborate preparation, in accomplishing that design.

The hook in the wing of a bat is strictly a mechanical, and also a *compensating*, contrivance. At the angle of its wing there is a bent claw, exactly in the form of a hook, by which the bat attaches itself to the sides of rocks, caves, and buildings, laying hold of crevices, joinings, chinks, and roughnesses. It hooks itself by this claw; remains suspended by this hold; takes its flight from this position: which operations compensate for the decrepitude of its legs and feet. Without her hook, the bat would be the most helpless of all animals. She can neither run upon her feet, nor raise herself from the ground. These inabilities are made up to her by the contrivance in her wing; and in placing a claw on that part, the Creator has deviated from the analogy usually observed in winged animals. A singular defect required a singular substitute.

The crane kind are to live and seek their food amongst the waters, yet, having no web feet, are incapable of swimming. To make up for this deficiency, they are furnished with long legs for wading, or long bills for groping; or usually with both. This is *compensation*. But I think the true reflection upon the present instance is, how every part of nature is tenanted by appropriate inhabitants. Not only is the surface of deep waters peopled by numerous tribes of birds that swim, but marshes and shallow pools are furnished with hardly less numerous tribes of birds that wade.

The common parrot has, in the structure of its beak, both an inconveniency and a *compensation* for it. When I speak of an inconveniency, I have a view to a dilemma which frequently occurs in the works of nature—namely, that the peculiarity of structure by which an organ is made to answer one purpose, necessarily unfits it for some other purpose. This is the case before us. The upper bill of the parrot is so much hooked, and so much overlaps the lower, that if, as in other birds, the lower chap alone had motion, the bird could scarcely gape wide enough to receive its food; yet this hook and overlapping of the bill could not be spared, for it forms the very instrument by which the bird climbs, to say nothing of the use which it makes of it in breaking nuts and the hard substances upon which it feeds. How, therefore, has nature provided for the opening of this occluded mouth? By making the upper chap movable, as well as the lower. In most birds the upper chap is connected, and makes but one piece, with the skull; but in the parrot, the upper chap is joined to the bone of the head by a strong ligament or membrane placed on each side of it, which lifts and depresses it at pleasure.

The spider's web is a *compensating* contrivance. The spider lives upon flies, without wings to pursue them; a case, one would have thought, of great difficulty, yet provided for, and provided for by a resource which no stratagem, no effort of the animal, could have produced, had not both its external and internal structure been specifically adapted to the operation.

In many species of insects the eye is fixed, and consequently without the power of turning the pupil to the object. This great defect is, however, perfectly *compensated*, and by a mechanism which we should not

suspect. The eye is a multiplying glass, with a lens looking in every direction, and catching every object; by which means, although the orb of the eye be stationary, the field of vision is as ample as that of other animals, and is commanded on every side. When this lattice-work was first observed, the multiplicity and minuteness of the surfaces must have added to the surprise of the discovery. Adams tells us that 1400 of these reticulations have been counted in the two eyes of a drone-bee.

In other cases the *compensation* is effected by the number and position of the eyes themselves. The spider has eight eyes, mounted upon different parts of the head; two in front, two in the top of the head, two on each side. These eyes are without motion, but by their situation suited to comprehend every view which the wants or safety of the animal render necessary.

The Memoirs for the Natural History of Animals, published by the French Academy in the year 1687, furnish us with some curious particulars in the eye of a chameleon. Instead of two eyelids, it is covered by an eyelid with a hole in it. This singular structure appears to be *compensatory*, and to answer to some other singularities in the shape of the animal. The neck of the chameleon is inflexible. To make up for this, the eye is so prominent, that more than half of the ball stands out of the head; by means of which extraordinary projection, the pupil of the eye can be carried by the muscles in every direction, and is capable of being pointed towards every object. But then, so unusual an exposure of the globe of the eye requires, for its lubricity and defence, a more than ordinary protection of eyelid, as well as a more than ordinary supply of moisture; yet the motion of an eyelid, formed according to the common construction, would be impeded, as it should seem, by the convexity of the organ. The aperture in the eyelid meets this difficulty. It enables the animal to keep the principal part of the surface of the eye under cover, and to preserve it in a due state of humidity without shutting out the light; or without performing every moment a nictitation, which, in all probability, would be more laborious to this animal than to others.

But the works of the Deity are known by expedients. Where we should look for absolute destitution, where we can reckon up nothing but wants, some contrivance always comes in to supply the privation. A snail, without wings, feet, or thread, climbs up the stalks of plants by the sole aid of a viscid humour discharged from her skin. She adheres to the stems, leaves, and fruits of plants by means of a sticking plaster. A mussel, which might seem by its helplessness to lie at the mercy of every wave that went over it, has the singular power of spinning strong tendinous threads, by which she moors her shell to rocks and timbers. A cockle, on the contrary, by means of its stiff tongue, works for itself a shelter in the sand. The provisions of nature extend to cases the most desperate. A lobster has in its constitution a difficulty so great, that one could hardly conjecture beforehand how nature could dispose of it. In most animals, the skin grows with their growth. If, instead of a soft skin, there be a shell, still it admits of a gradual enlargement. If the shell, as in the tortoise, consists of several pieces, the accession of substance is made at the sutures. Bivalve shells grow bigger by receiving an accretion at their edge; it is the same with spiral shells at their mouth. The simplicity of their form admits of this. But the lobster's shell being applied to the limbs of the body, as well as to the body itself, allows not of either of the modes of growth which are observed to take place in other shells. Its hardness resists expansion, and its complexity renders it incapable of increasing its size by addition of substance to its edge. How, then, was the growth of the lobster to be provided for? Was room to be made for it in the old shell, or was it to be successively fitted with new ones? If a change of shell became necessary, how was the lobster to extricate himself from his present confinement?—how was he to uncase his buckler, or draw his legs out of his boots? The process which fishermen

have observed to take place is as follows:—At certain seasons the shell of the lobster grows soft; the animal swells its body; the seams open, and the claws burst at the joints. When the shell has thus become loose upon the body, the animal makes a second effort, and by a tremulous spasmodic motion, casts it off. In this state the liberated but defenceless fish retires into holes in the rock. The released body now suddenly pushes its growth. In about eight-and-forty hours, a fresh concretion of humour upon the surface—that is, a new shell—is formed, adapted in every part to the increased dimensions of the animal. This wonderful mutation is repeated every year.

In the changing of the colour of the chameleon, we see one of the beautiful compensatory provisions of nature. This little animal, which is common in the East Indies and some other Asiatic countries, lives upon flies, beetles, or other insects, which it catches by climbing up shrubs or trees, and darting out its tongue; but its pace is slow, and as insects have good eyes to perceive the approach of an enemy, they would be sure to make their escape in the present case, unless the chameleon approached them in disguise. This, therefore, it invariably does. As it passes among green leaves, it is of a green colour; and when it glides by any of a red or yellow tinge, so does it change its hue to red or yellow. So closely does it assume not only the shades and colours, but even the shapes of the leaves around, that a spectator might look among the foliage for some minutes before discovering it.

By carrying our observation upward from the mere physical organisation of man, to the *mind* which he possesses, and is able to exert in reference to both sensible objects and abstract subjects, we have still greater reason to admire the proofs of design and goodness in an overruling Creator; for we all feel that this principle of mind—how constituted we do not here stop to inquire—is in harmony with the other works of creation around us. For example, how much are our minds suited to the recognition of what is beautiful and harmonious in nature and art. This, however, admits of a few separate observations:—

#### Beauty.

The wisdom of the great original Contriver is eminently manifested in that property of inanimate and animate objects which we call beauty. Here there is an evident fitness between the taste and habits of animals, human beings included, and what can be seen by the eye. We feel pleasure in contemplating the works of nature most obvious to our senses; and we cannot but remark, that that which is loathsome is not ordinarily presented to the eye. The splendid colouring of the vegetable kingdom, the smooth or spotted skins of the brute creation, and the lovely plumage of the feathered tribe, all give us delight in the contemplation. Consider, also, how beautiful is the outward appearance of the human form. Reflect on what the parts and materials are of which the fairest body is composed, and no further observation will be necessary to show how well these things are wrapped up, so as to form a mass which will be capable of symmetry in its proportion, and of beauty in its aspect; how the bones are covered—the bowels concealed—the roughness of the muscle smoothed and softened; how over the whole is drawn an integument, the skin, which converts the disgusting materials of a dissecting-room into an object of attraction to the sight, or one upon which it rests at least with ease and satisfaction.

The more minutely that we inspect the works of nature, the greater cause have we to wonder at the extraordinary perfection and beauty everywhere prevalent. The microscope develops splendours in the creation of insects which we can hardly comprehend. The back of a diamond-beetle exhibits an assemblage of brilliant colours and glittering gems more splendid than any artificial arrangement of the most precious stones. The colours of the feathers of birds in tropical climates, and the skins of the fishes of Ceylon, are in-

comparable to their beauty. And why is all this the case? Because it yields a pleasure to the sight, both of men and other living creatures; for the Creator has not denied the feeling of delight to the meanest reptile which crawls. All is beautiful, it would appear, in the estimation of one or other of living creatures. The most insignificant little flower, now blooming far from the haunts of men, in some remote wilderness, does not, as has been said, waste its sweetness on the desert air. It furnishes an object of pleasing gratification to some description of sentient creatures, perhaps so small as to be imperceptible to our naked eye.

Placing agreeableness of aspect entirely out of the question, there is another purpose answered by the skin—and that is concealment. Were it possible to view through this integument the mechanism of our bodies, the sight would frighten as much as it would disgust us. Durst we make a single movement, or stir a step from the place we were in, if we saw our blood circulating, the tendons pulling, the lungs blowing, the humours filtrating, and all the incomprehensible assemblage of fibres, tubes, pumps, valves, currents, pivots, which sustain an existence at once so frail and so presumptuous?

In clothing the human frame with a covering of skin, the Creator has not omitted to vary its character according to local necessities. The skin is most beautiful on the face, because the face is most exposed to observation; it is softest where least liable to injury, and hardest or firmest in texture where it is most subject to be pressed upon. There is not less sign of contrivance in the manner in which it ceases at the extremities of the toes and fingers. A man has only to look at his hand, to observe with what nicety and precision that covering, which extends over every other part, is here superseded by a different substance and a different texture. Why do we find the skin cease at our fingers' ends, or on the back part of the fingers, and not the fore part? Because something hard or horny was required on these parts, by which we could hold fast or lift nimbly objects which we wished to grasp or seize upon. Nails, therefore, supersede the skin on such places. The same forethought is visible in the covering of our heads. What could have been a more beautiful or appropriate substance wherewith to cover the head and preserve the hard bony skull from injury, than the hair, a substance at once light, warm, and graceful?

#### DESIGN IN VEGETABLE PHYSIOLOGY.

In accordance with our intentions in glancing through most of the natural sciences, and bringing home to the main object of our labours treasures illustrative of design from them all, let us now turn our attention to those afforded by the vegetable kingdom of nature. And first, of the mutual relations that exist between animals and vegetables; in considering which, we shall find that these two great organised kingdoms of the creation are made to co-operate in the execution of the same design; each ministering to the other, and preserving that due balance in the constitution of the atmosphere which adapts it to the welfare and activity of every order of beings, and which would soon be destroyed were the operations of any one of them to be suspended. 'It is impossible to contemplate so special an adjustment of opposite effects without admiring this beautiful dispensation of Providence, extending over so vast a scale of being, and demonstrating the unity of plan on which the whole system of organised creation has been devised.' We said in a former part of this essay that two principles of atmospheric air were oxygen and carbon; that the former was as essential to animal life as the latter was obnoxious to it; but that, on the other hand, carbon was indispensable to the continuance of vegetable organisations. We will now endeavour to explain this by a short account of the phenomena of respiration, as displayed in the two kingdoms.

Among animals, the function of respiration is that by which the blood, received into its vessels from the alimentary canal, is, during its subsequent circulation,

kept in a state of requisite purity. This is in all cases effected by bringing it at intervals into contiguity either with atmospheric air alone, or with water containing this air diffused through it; when such is the mutual action of the blood and the air upon each other, that the former is purified, and passes in general from a dingy purple to a bright scarlet colour, while the latter is in the same degree rendered impure, and after a time becomes inadequate to support either respiration or combustion. Now whether the aerating organs be lungs or gills, it appears to be the object of nature in their construction to expose a large surface to the contact of air. This object is accomplished by their division into numerous cells or leaf-like processes, or by their extension on the walls of cavities, or the surface of pectinated ridges. The blood brought to these organs is there distributed by their terminating branches. Although still retained in vessels, it can nevertheless be easily acted upon by the air on the exterior. Priestley found the colour of blood changed by the air when enclosed in a moistened bladder, and the same effect was observed by Hunter when it was covered with goldbeaters' skin. It is scarcely possible to determine by direct observation what is the exact nature of the changes that the blood undergoes in its passage through the lungs: the most obvious is its change of colour; and the chemical differences between the dark purple blood in the veins before it has reached the lungs, and the bright vermilion colour it exhibits in the arteries after it has circulated through the lungs, and been exposed to the influence of the air, may be collected from the changes made in the air itself. Atmospheric air is known to consist of certain principles in definite proportions; when it has acted upon the blood, and is returned from the lungs, it is found that a certain proportion of oxygen which it contained has disappeared, and that the place of this oxygen is almost wholly supplied by an addition of carbonic acid gas and watery vapour. The exact quantity of oxygen which is lost in natural respiration varies in different animals, and even in different conditions of the same animal. Birds, for instance, consume larger quantities of oxygen by their respiration, and hence require, for the maintenance of life, a purer air than other vertebrated animals. Vauquelin, however, found that many species of insects and worms possess the power of abstracting oxygen from the atmosphere in a much greater degree than the larger animals; thus snails are capable of living for a long time in the vitiated air in which a bird had perished. Some insects which conceal themselves in holes, or burrow under ground, have been known to deprive the air of every appreciable portion of its oxygen. It is observed by Spallanzani, that those animals whose modes of life oblige them to remain for a great length of time in these confined situations, possess this power in a greater degree than others which enjoy more liberty of moving in the open air; so admirably have the constitutions of animals been in every instance accommodated to their respective wants.

Now bearing in mind that the air coming in contact with the blood of animals parts with its oxygen, and receives in its place carbonic acid gas, let us consider the function of respiration, or, more properly, aëration, as it occurs in vegetables. It was necessary that some means should be appointed by which this great quantity of carbon given out into the air by animals, and so injurious to animal life, should be removed from it. We have said that this principle was necessary to vegetable life; and here we find the means not only by which, in a very considerable degree, it is procured, but also by which it is removed from the atmosphere. The leaves of plants are analogous to the lungs of animals, and it is in them principally that the decomposition of the carbonic acid absorbed from the air is effected. When exposed to the action of the sun, they decompose that gas, retain its carbon, and disengage its oxygen. Solar light is an essential agent in effecting this chemical change; for it is never found to take place at night,

nor while the plant is kept in the dark. That the carbon resulting from this decomposition of carbonic acid is retained by the plant, has been most satisfactorily proved by the experiments of Saussure, who found that this process is attended with a sensible increase in the quantity of carbon which the plant had previously contained. 'Thus the great object to be answered by this vegetable aëration,' says Dr Roget, speaking at considerable length of this undeniable evidence of design to which we have thus shortly alluded, 'is exactly the converse of that which we see effected by the respiration of animals; in the former, it is adding carbon to the vegetable organisation; in the latter, it is that of discharging the superfluous quantity of carbon from the animal system. On the whole, therefore, the atmosphere is continually receiving from the vegetable kingdom a large accession of oxygen, and is at the same time freed from an equal portion of carbonic acid gas, both of which effects tend to its purification, and to its remaining adapted to the respiration of animals.'

We have not much space to devote to the contemplation of vegetables, but we are unwilling to leave the subject without alluding to some other evidences of design which we find displayed in them. Among these, nothing more beautifully demonstrates that nature, or rather the Almighty Creator of nature, proceeds on a uniformity of plan and design, than the fact that plants, as well as animals, are possessed of the means of reproducing and continuing their species. The pistil which occupies the centre of the flower is destined to produce the seeds, while the stamens of the plant contain the dust necessary for fertilising them, and without which the seeds would not produce young plants. Nature has guarded with nice care this precious dust, for on its preservation depends the continuance of the species. The apparatus by which in many flowers it is defended from injury, is very curious; nor are the means that are provided by which it comes in contact with the stigma of the pistil less demonstrative of a great, a wise, and a beneficent Providence. In some plants where the organs are in the same flower, the stamens are placed above the stigma, upon which the dust, or pollen, falls by its own gravity; in others, we find the contrary is the case, the pistil being the longest; but here the flower is generally drooping. To assist the emission of the pollen, and its contact with the stigma, in many plants the stamens possess a very apparent moving power. When ripe, the ten stamens of the rue are seen alternately to bend down upon the stigma, deposit their portion of pollen, and return to their former position. The stalks or filaments of the pelitory of the wall are possessed of a remarkable elasticity, and thus forcibly scatter the pollen. This is very apparent if touched by the point of a needle; immediately it acts with a jerk, which dashes the pollen with some force on the stigma. The same arrangement is met with in the hbarberry bush, in which the six stamens remain sheltered under the concave tips of the flower-leaves or petals, till some extraneous body, as an insect in search of honey, touches the filament, which instantly contracts, and also dashes the pollen against the stigma. But all plants have not their stamens and pistils sheltered under the same veil; in many they are in different flowers, and in others even placed on different plants. Here, again, we have to admire the wise measures nature has taken for the accomplishment of her designs. In many, the scattering of the pollen is effected by the winds; to favour the access of which we find in some, as the hazel, the leaves are not evolved until after the seed has been perfected; or, if the plants be evergreens, the leaves are needle-shaped, so as to present very little obstacle to the passage of the pollen, which is secreted in much larger quantity than usual. Various species of insects, and especially the bee, are selected by nature for this purpose. In the pink we observe numerous small insects creeping to and fro, and thus depositing the pollen on the stigma. In flowers where the stamens and pistils are on different plants, often at a considerable distance

from each other, bees, and other flying insects, are peculiarly accessory to the great end of nature. These insects, it is true, do not visit the flower for the purpose of scattering the pollen; they only seek for the sweet juice which exudes from its nectary. Their hairy body, which nature did not bestow without design, is seen covered with pollen, often in such quantities as to impede the progress of the animal; this, whenever they visit another flower, is rubbed against the stigma; and it is a fact, no less wonderful than calculated to fill us with admiration at the wise provision of nature, that many insects are peculiarly attached to one flower, and that others, as the bee, will only visit one species in each journey from its hive.

The various methods which nature employs to disperse the different varieties of seeds over the earth are truly wonderful. Many plants, when the seed is fully ripe, discharge it from its covering with a jerk or elastic spring. The common oat is thrown out in this way; and the loud crackling of the pods of the broom in a dry sunshiny day, or, as Drummond has it, 'bursting seed-balls crackling in the sun,' is caused by their bursting and scattering about the contained seeds, and must have been frequently noticed. 'Who has not listened,' again asks Sir James Edward Smith, 'in a calm and sunny day, to the crackling of the furze bushes, caused by the explosion of their elastic little pods; or watched the down of innumerable seeds floating on a summer breeze till they are overtaken by a shower, which, moistening their wings, stops their farther flight, and at the same time accomplishes its final purpose, by immediately promoting the germination of each seed in the moist earth? How little are children aware, when they blow away the seeds of the dandelion, or stick burs in sport upon each other's clothes, that they are fulfilling one of the great ends of nature!' These downy appendages to which Sir J. E. Smith alludes, buoy up the lighter seeds, as the thistles, and carry them floating through the air to great distances. Then there are the currents of rivers which bear the seeds from one part of the country to another; and even seas and oceans, whose tides and currents float along the germs of vegetation to the various regions of the globe. Birds, too, by feeding on particular seeds, carry them to great distances, where, being often voided entire, they vegetate. There is evident design in all this. It could not have been by mere chance that in flowers which stand erect, the pistil is shorter than the stamens, permitting the pollen as it falls to descend upon the stigma; and when the flower is drooping, that the contrary arrangement is effected.

It is not here out of place to remark, that there is scarcely a vegetable production on which some species of animal does not subsist; and, generally speaking, wherever that peculiar production is to be found, there also is the animal to which it furnishes wholesome food. With some striking examples of this kind the most uneducated man is acquainted: he knows that the partridge is on the plain, the woodcock in the forests, the grouse on the moors, and the ptarmigan on the loftiest peaks of the mountains. He knows, too, that other species migrate from country to country, seeking their food in distant regions, over trackless oceans, when it fails in their native haunts; and, among the animal kingdom, so universal is this, as to form an example of the wonderful adaptations which exist between it and the vegetable world. Vegetables, like animals, are adapted to varieties of climate and temperature; and when we consider their distribution over the globe, we shall find that those which are most essential to the maintenance of man, bear a variety of climate better than most others. This is the case with greens, carrots, potatoes, and many kinds of grain. Warm climates are much more favourable to vegetation than cold. In Spitzbergen, the whole number of plants with conspicuous flowers, natives of the country, is found by botanists scarcely to exceed thirty species; while in the warmer regions of the West Indies, in Madagascar and the coast of Coromandel, Willdenow enumerates from

four to five thousand different species of indigenous plants. Now observe how admirably this distribution of plants corresponds with the wants and necessities of man. A vegetable diet is most suitable both to the tastes and the actual needs of the inhabitants of warm climates, and there we find that kind of food most abundant.

It is impossible for a reflecting individual to walk beside a field of growing barley without being impressed with the conviction that, in the economy of this description of grain, the design of a Creator has been wonderfully manifested. An ear of barley differs from one of wheat or oats. Each of the grains is furnished with a long slender bristle or beard, which is prickly to the touch, and seems to serve as a protection to the ear. These bristles form a roof, if we may so call it, to carry off the rain from the ear, and yet, by their elegant disposition, do not prevent the heat of the sun and the light from influencing the grain. And why should such be the case with barley, when the ears of wheat, oats, &c. do not possess any such protective process? Because barley is a grain easily injured by wet, which, if not carried off, would cause the ear to sprout even while on the stalk, and consequently be entirely useless to man.

In speaking of the economy of vegetable life, it should not pass unnoticed that there is a remarkable instance of Creative Wisdom in the means which have been arranged for the growth of plants from putrescent matter. All kinds of vegetable and animal substances, when deprived of life, as well as excrementitious matter, have a tendency to decomposition—that is, to resolve themselves into those elementary gases of which they have been chiefly composed. This process of dissolution, as every one knows, produces a most disagreeable odour, which is often inimical to animal life. But this is not an evil; it displays a bountiful provision in nature; for it tells us, in a way not to be misunderstood, that the substance undergoing, or about to undergo, the putrefactive process, should be buried underground; and being there deposited, it immediately proceeds to supply its no longer useful gases to the infant plants and crops of grain which flourish on the surface. Thus do we see another striking evidence of the harmonious design which everywhere prevails between the animal and the vegetable creation.

It has been said that a vegetable diet is preferred by the inhabitants of warm countries: to them sobriety is an easy virtue, and a happy consequence of the climate. The people of northern regions, on the contrary, are voracious from instinct and necessity. They swallow enormous quantities of food, and prefer those substances which in digestion produce the most heat. Obligated to struggle incessantly against the action of cold, their life is but a continual act of resistance to external influences. Let us not reproach them with voracity, and their avidity for ardent spirits and fermented liquors. Those nations which inhabit the confines of the habitable world, in which man is scarcely able to withstand the severity of the climate, the inhabitants of Kamtschatka, the Samoiedes, &c. live on fish that, in the heaps in which they are piled up, have already undergone a certain degree of putrefactive fermentation. In them there is a necessity for this inward excitement, which in our climate would be inevitably attended with disease, and probably death. The abuse of spirituous liquors is fatal to the European transported to the burning climate of the West Indies. The Russian drinks spirituous liquors with impunity, and lives on to an advanced age, amidst excesses under which an inhabitant of the south of Europe would sink.

The influence of climate not only affects alike the regimen of man in health, but of man in sickness; and it has been justly observed of medicine, that it ought to vary according to the places in which it is practised. A few substances, for the most part obtained from the vegetable kingdom, sufficed to Hippocrates in the treatment of diseases; and physicians who practise in a climate such as Greece, may imitate the simplicity of the father of medicine. Opium, bark, wine, spirits, aromatics, and the most powerful cordials, are, on the other

and, the medicines suited to the inhabitants of northern latitudes; and thus they are enabled to use freely those medicines which elsewhere would be attended with the utmost danger.

We are now prepared to understand the beautiful and wonderful harmony that exists between the distribution of man and plants over the globe; and no one, we think, can deny their meed of praise and admiration for the care and beneficence which this universal adaptation exhibits. The frigid zone contains but few species of plants, and the verdure of those countries which lie within the polar circle is confined chiefly to the hills having a southern aspect, and the trees are of very diminutive growth. Besides mosses and lichens, there exist ferns, creeping plants, and some shrubs yielding berries of an agreeable flavour. The Arctic regions of Europe are peculiarly favoured; for in certain parts of Lapland there are fine forests, and even rye and leguminous plants are produced. In the high latitudes of the northern temperate zone are the pine and the fir, which show their adaptation to a cold climate by retaining their verdure in the midst of the regions of winter. To these, as advancing southward, succeed the oak, the elm, the beech, the lime, and other forest-trees. Several fruit-trees, among which are the apple, the pear, the cherry, and the plum, grow better in the northern half of this zone; while to its more southern parts, especially, belong the more delicate fruits, such as the olive, the lemon, the orange, and the fig; and among trees, the cedar, the cypress, and the cork. The space comprised between the 30th and the 50th parallels of latitude may be considered as the country of the vine and the mulberry. Wheat extends as far north as the 60th degree; oats and barley a few degrees farther. In the southern parts of this zone, maize and rice are more commonly cultivated. The vegetation of the torrid zone is characterised by a richness, a variety, and a magnificence which are nowhere to be found in the regions of the globe. Under the beams of a tropical sun, the most juicy fruits arrive at perfection; and innumerable productions supply the wants, and administer to the luxuries of man. There the grounds yield the sugar-cane, the coffee-tree, the palm, the pine-apple, the cotton-tree, the bread-tree, the pisang, the immense baobab, the date, the cocoa, the vanilla, the cinnamon, the nutmeg, the pepper, the camphor, and numerous other fruits and aromatics.

CONCLUSION.

But we must hasten to conclude our interesting subject. Illustrations of design might be produced from the works of nature without end; every link in the chain of creation teems with proofs of it; in none can any one affirm with truth that it is wanting. Cursory as our remarks have been, they still must lead to the general conclusion that not only design, but unity of design, and identity of operation, pervade the works of nature, in as far as relates to organised existences; and even among those portions of creation which are not organic, there do we find the same evident desire and design to render them subservient to the wants and necessities of those which are. To several of these we have alluded, though it did not accord with our plan to allude to all; and we need only further draw attention to the remarkable uniformity in the plan of creation. The universe itself is a system; each part depending upon other parts, or being connected with other parts by some common law of motion, or by the presence of some common substance. One principle of gravitation causes a stone to drop towards the earth, and the moon to wheel round it. One law of attraction carries all the different planets round the sun. New countries are continually discovered, but the old laws of nature are always found in them—new plants perhaps, or animals, but always in company with plants and animals which we already know, and always possessing many of the same general properties. We never get amongst such original or totally different modes of existence, as to indicate that we are come into the

province of a new Creator, or under the direction of a different will. In truth, the same order of things attends us wherever we go. There is everywhere a perfect uniformity in the laws which regulate the phenomena of nature. And this very fact, while forcibly illustrating the unity of that Power by whose instrumentality all that we see was ordered and originated, demonstrates most strikingly at the same time the surpassing wisdom of the same creative Being. What agency, but one endowed with omniscience, could have educated results so mighty from a few simple and uniform laws!—could have instituted and set in action these laws at the first, assured that, without change, or shadow of change, they would fulfil to the last all the great objects connected with the progressive development of the scheme of the universe! Thus all that we behold around us, all that we can learn of nature, impresses us with a sense at once of the unity, omniscience, power, and goodness of the creative Being.

ETHICS.

A knowledge of the great truth which we have attempted to demonstrate, forms the foundation of Ethics, or Moral Philosophy, which may be defined to be 'the science which treats of our obligations and duties as moral and responsible agents.' These duties it has been customary to comprehend under three divisions—the duties which we owe to God, to our fellow-creatures, and to ourselves. It must not be supposed, however, that these several departments of duty, although arranged under different heads, are in the slightest degree opposed to one another. The very reverse is the case. They all harmonise together; and he, for example, who acts towards other men as he would wish them to act towards himself, affords the surest guarantee that he cherishes a due love and veneration for the Supreme Being, and that he entertains enlightened views regarding his own best interests; whereas of him who neglects the duties of justice, benevolence, and mercy, it may be truly said that he is destitute of those feelings which he ought to cherish towards the great Author of his being, and that he neglects the means by which his own happiness may be most effectually secured.

Considerable difference of opinion has existed regarding what has been termed 'the moral sense'—the generality of moralists contending that it is a principle implanted in us by the hand of nature, while others maintain that it is merely the result of cultivation and experience. There can be very little doubt, we apprehend, that the generally received opinion upon this subject is the correct one; for we cannot very easily conceive how, by any amount of cultivation, an important principle could be evolved out of a nonentity, or how it could be generated by the most varied experience, had not the germ of it previously existed in the human constitution. The advocates of the opposite opinion, however (among whom must be reckoned a distinguished ornament of ethical science, the soundness of whose moral principles at least has never been called in question), have apparently too much ground for the conclusion which they have arrived at. We see many atrocious criminals who seem to have cast off all moral restraint, and who act in such a manner as if they were totally unconscious of any distinction between right and wrong; and there are whole tribes of the human family to be found who appear to be immersed in such gross barbarism as to be utterly incapable of comprehending any such distinction. But we must not infer that in either of these cases the moral principle is altogether wanting. In neither, it is true, is it properly developed: but in the one case it is blunted and overborne by habits of lawless depravity; and in the other it has never been able to spring up into maturity, in consequence of the want of some friendly hand to pluck up the weeds, and to root out the briars which choke and impede its growth. In neither case is it dead: it only sleepeth; and by

the application of the proper remedy the reckless criminal may be made an exemplary member of society, and the ignorant and untutored savage may become acquainted with the blessings of civilisation. No: there is no human being, however immersed in ignorance, however degraded by crime, who is entirely devoid of this principle. Circumstances may indeed obscure it for a time, but it can never be altogether extinguished. Even the rudest barbarian knows that there is a Being infinitely superior to himself, to whom he owes homage and allegiance, however imperfect may be his conceptions of the character of that Being, or of the nature of the allegiance which is due to Him. This is sufficiently attested by the fact, that in those countries where no rational system of religion exists, a multitude of superstitious ceremonies and observances have been substituted in its place.

But how does even civilised man arrive at the knowledge of moral relations! The mere circumstance of his believing in the existence of an almighty, wise, and beneficent Being, who at first created, and still continues to uphold, the world, does not necessarily imply that he deems it his duty to worship and to serve that Being. Before he can be made aware of this necessity, the moral sense must be aroused; and this can be effectually done only by the cultivation and enlargement of his intellectual faculties. Before an individual can rationally worship God, he must be conscious of the relation in which he stands to Him; he must feel that God is his creator and preserver. By observing the traces of design discernible in the material universe, he is necessarily led to conclude that it is the work of a designing mind; and when he discovers the admirable adaptation of external nature to his own constitution, physical, intellectual, and moral, the inference is unavoidable, that the same Being who created the one also formed the other. After he has been enabled to arrive at this conclusion, the moral sense comes immediately into exercise; and he will then feel it to be his duty to love and obey the great Author of his existence, who has made such bountiful provision for the supply of his wants and for the gratification of his desires. And the more he discovers of these wonderful adaptations, the more will his sense of the obligations he is under to the Deity be increased, and consequently the greater will be his ability to love and serve Him. We could feel no affection for a Being on account of his having bestowed existence upon us, if mere existence had been the only circumstance for which we were indebted to Him. He might have created us for the express purpose of rendering us miserable; and then, according to the present constitution of our nature, instead of being disposed to love and venerate a Being so malignant, we must unavoidably have regarded Him with horror and detestation. The sense of benefits conferred is an essential pre-requisite to the feeling of gratitude; and it is therefore evident that the untutored savage cannot entertain such a lively degree of this feeling towards the Almighty, as the man of cultivated intellect, who can penetrate into the secrets of nature, and trace out its adaptations to the necessities of his own complicated existence. The former may indeed feel an emotion of gratitude to the 'Great Spirit' for his success in war or in the chase, or for those spontaneous productions of the earth which supply his bodily wants and contribute to his animal gratification; but the man of cultivated taste can experience an exquisite enjoyment in contemplating the beauties of creation, and can appreciate the Divine goodness in furnishing him with the means of such enjoyment. And those phenomena of nature which terrify the savage, and cause him to have recourse to the most unmeaning ceremonies to avert the wrath of an angry and avenging Spirit, are regarded by the philosopher as the procedure of a wise and beneficent Being, who makes the elements the ministers of his pleasure, and sends forth the tempest and whirlwind for the purpose of clearing away those noxious exhalations which engender disease and death. We do not mean to affirm that the

highly-cultivated theist will actually be disposed to cherish towards the Deity deeper feelings of veneration, gratitude, and love, than the rude illiterate barbarian; but we have no hesitation in asserting, that from his acquaintance with external nature, and its nice adaptations to the peculiar constitution of man, the former will be rendered more capable of entertaining such feelings than the latter; and that the farther this acquaintance is extended, the more will this capability be increased.

The same acquaintance with external nature, and with its adaptation to his own state and circumstances, by which man acquires a knowledge of the duties which he owes to God, teaches him also those duties which he owes to himself and his fellow-creatures; and if he is anxious to promote his own happiness, he will feel the necessity of acting in conformity with the system which God has appointed. The Deity could have had no other end in view, in the formation of any of His creatures, than the benevolent one of rendering them happy; and He has instituted certain laws, by an adherence to which this important purpose will be most effectually accomplished. Whenever, therefore, man acts in accordance with the appointment of the Supreme Ruler of the universe, he fulfils the great end and object of his being, and consequently will enjoy that happiness of which his nature is susceptible; but when he acts in opposition to that appointment, he will necessarily experience suffering and misery—for no institution of the Deity can be violated with impunity.

But man is not an isolated being: he is a member of a great community of creatures of a nature similar to his own; and he feels that between them and himself there exists a mutual relation. Hence arises the conception of that order of duties which he owes to his fellow-creatures. It is a part of the Divine plan that all the members of the human race should live in harmony together; and in accordance with this plan, it is necessary that each should do everything in his power to promote the welfare of others, and that all should practise those virtues which are essential to the very existence of civil society. Now were each individual of the human family to be actuated solely by selfish motives, and were all to neglect or violate, without scruple, the virtues and duties of social life, then it is evident that the order of society would be deranged, the Divine plan for the happiness of the human race would be defeated, and universal suffering to individuals and communities would be the inevitable result. By the faithful discharge of these duties, on the other hand, the harmony and prosperity of mankind would be promoted, individual happiness would be secured, and the most acceptable homage would be rendered to the Deity; who, having instituted certain laws for the guidance and regulation of His creatures, is gratified or displeased with them in proportion as they observe or violate His wise and beneficent appointments.

Thus we see that all the departments of man's duty are inseparably connected together, and that the faithful discharge of one class of these duties naturally leads to the performance of all the rest. And as a knowledge of these duties, in as far as it is attainable by the unaided light of reason, is to be learned from a diligent observation of the laws of nature, and of man's relation to them, it is the duty of every human being carefully to study these laws, and to use his utmost endeavours to bring his conduct into conformity with them. Were such conduct to become universal, all strife and animosity would be brought to an end; the whole members of the human family would be knit together in one common bond of brotherhood; and that peace, prosperity, and happiness which are only to be found in the fabled descriptions of the Golden Age, would overspread and gladden the earth. Beyond this, Natural Theology and Ethics, even in their highest and purest conceptions, cannot lead: the causes which retard such a consummation, the Divine scheme for their removal, and a knowledge of man's future destiny, belong to religion as revealed in the BIBLE—the history of which forms the subject of our following number.

# HISTORY OF THE BIBLE—CHRISTIANITY.

THE Bible is the most remarkable work now in existence. In the libraries of the learned there are frequently seen books of an extraordinary antiquity, and curious and interesting from the nature of their contents; but none approach the Bible, taken in its complete sense, in point of age; while certainly no production whatever has any pretension to rival it in the dignity of composition, or the important nature of the subjects treated of in its pages. The word *Bible* is of Greek origin, and in signifying simply the *Book*, is expressive of its superiority over all other literary productions. The origin and nature of this in everyway singular work—how it was preserved during the most remote ages, and how it became known to the modern world in its present shape—form a highly-interesting chapter of literary history.

## OLD TESTAMENT.

The Bible comprehends the foundation of the religious belief of the Jews and Christians, and is divided into two distinct portions, entitled the Old and New Testament, the former being that which is esteemed by the Jewish nation, but both being essential in forming the faith of the Christian. The Old Testament is the largest department of the work, and appears a collection of detached histories, moral essays, and pious poetical compositions, all placed together in the order of time, or as they may serve for the purpose of mutual illustration. On taking a glance at the contents, the principal subject of narration seems to be the history of the Jews, commencing with an account of the creation of the world, and tracing their history, genealogically, through a series of striking vicissitudes and changes of situation. But when we examine the narratives minutely, it is found that there is another meaning than that of mere historical elucidation. It is perceived that the whole train of events recorded, and the whole of those lofty impassioned strains of poetry which distinguish the volume, are precursory and prophetic of a great change which, at a future period, was to be wrought on the moral character and fate of mankind, by the coming to the earth of a Messiah.

The authorship of the Old Testament has been universally ascribed, by both Jews and Christians, to pious men, who were inspired or influenced by God to communicate to the world a correct knowledge of the foundations of religious belief and moral obligation. The Bible is hence called the Revealed Word of God, or the Sacred Scriptures. 'We are to look to the Word of God, then,' says the writer of the article THEOLOGY in the 'Edinburgh Encyclopedia,' 'as contained in the Scriptures of the Old and New Testaments, for the only sure rule of faith and practice. But there is this singularity in the Sacred Scriptures, that we do not find in them a set treatise on any one of the interesting subjects which engage our attention as moral and religious beings. No attempt is made to prove the existence of a God: such an attempt would have been entirely useless, because the fact is universally admitted. The error of men consisted not in denying a God, but in admitting too many; and one great object of Scripture is to demonstrate that there is but one. No metaphysical arguments, however, are employed for this purpose. The proof rests on facts recorded in the history of the Jews, from which it appears that they were always victorious and prosperous so long as they served Jehovah, the name by which the Almighty made himself known to them; and uniformly unsuccessful when they revolted from him to serve other gods. What argument could be so effectual to convince them that there was no God in all the earth but the God of Israel! The sovereignty and universal providence of the Lord Jehovah

are proved by predictions delivered by the Jewish prophets, pointing out the fate of nations and of empires, specifying distinctly the cause of their rise, the duration of their power, and the reason of their decline; thus demonstrating that one God ruled among the nations, and made them the unconscious instruments of promoting the purposes of His will.

The writers, generally speaking, do not reason, but exhort and remonstrate; they do not attempt to fetter the judgment by the subtleties of argument, but to rouse the feelings by an appeal to palpable facts. But though there is no regular treatise in the Scriptures on any one branch of religious doctrine, yet all the materials of a regular system are there. The Word of God contains the doctrines of religion in the same way as the system of nature contains the elements of physical science. In both cases the doctrines are deduced from facts, which are not presented to us in any regular order, and which must be separated and classified before we can arrive at first principles, or attain to the certainty of knowledge; and in both cases a consistent system can only be made out by induction and investigation. The very circumstance of no detailed system being given, renders it necessary to form one; for although a portion of religious and physical knowledge, sufficient for the common purposes of life, may be obtained by traditional information, and men may work conveniently enough by rules without possessing much general knowledge, yet they who would teach with profit, must generalise, and they who would explain the ways of God, must arrange the materials which are so amply furnished, but which are presented apparently without order or plan.'

The periods when the act of writing all or greater part of the Scriptures took place, as well as most of the names of those who were instrumental in forming the work, have been ascertained with considerable accuracy, both from written evidence in the narratives themselves, and from the well-preserved traditions of the Jews. Generally speaking, it cannot be said that the books of the Old Testament are of a less antiquity than from two thousand three hundred to four thousand years—an antiquity considerably greater than that of any profane history. At whatever time, however, the different books were written, they were not collected from the sacred depositories of the Jews, where they had been carefully placed, till long after their immediate authors were deceased; and their present arrangement, as we shall afterwards explain, is of comparatively modern date.

From an early period it was the custom of the Jews to divide the books of the Old Testament into three classes, which they respectively designated the *Law*, the *Prophets*, and the *Hagiographa*, or *Holy Writings*, which last division includes more particularly the *poetical parts*; and some are of opinion that Jesus Christ alludes to this division of the Scriptures, when he says that 'All things must be fulfilled that were written in the *Law of Moses*, and in the *Prophets*, and in the *Psalms*, concerning him.' For by the book of *Psalms* they understand all the books of the third class. The *Law* comprehends the *Pentateuch*—that is, Genesis, Exodus, Leviticus, Numbers, and Deuteronomy—such including both a historical narrative, and the injunctions forming the legal code of the Jews. The *poetical books* are eight—namely, 1. *Joshua*; 2. *Judges*, with *Ruth*; 3. *Samuel*; 4. *Kings*; 5. *Isaiah*; 6. *Jeremiah*; 7. *Ezekiel*; and 8. The *Twelve Lesser Prophets*. The first four books of this division are called the *Former Prophets*, and the last four the *Latter Prophets*. The *Hagiographa*, or *Holy Writings*, are nine—namely, 1. *Job*; 2. The *Psalms*; 3. The *Proverbs*; 4. *Ecclesiastes*;

5. *The Song of Songs*; 6. *Daniel*; 7. *Chronicles*; 8. *Ezra*, with *Nehemiah*; and 9. *Esther*.

According to the order in which the books of the Old Testament now stand, those of a historical nature are appropriately placed at the beginning. The first five books, having a chain of connection throughout, are Genesis, Exodus, Leviticus, Numbers, and Deuteronomy. These are styled the *Pentateuch*, such being the Greek compound for *five books*. They are likewise entitled the Books of Moses, from the belief that that enlightened Jewish leader composed them.

The Jews, or Hebrews, take the name of the sacred books from the first word with which each begins; but the Greeks, whom our translators generally follow, take the names from the subject-matter of them. Thus the first book is called by the Hebrews *Bereishith*, which signifies *In the beginning*, this being the first word; but the Greeks call it *Genesis*, which signifies *Production*, because the creation of the world is the first thing of which it gives an account. It likewise contains an account of the increase of mankind; of their corruption of manners, and its cause; of their punishment by the Deluge; of the origin of the Jewish people from Abraham; of the manner in which God was pleased to have them governed; and particularly of the nature of the special superintendence vouchsafed to the Jewish nation by the Creator. This comprehensive narrative reaches from the creation of the world till the death of Joseph, or a period of 2369 years. (See CHRONOLOGY.)

*Exodus*, the title of the second book of Moses, signifies in Greek *The going out*, and was applied from the account which it gives of the Israelites going out of Egypt. In it are related the cruel Egyptian slavery under which the Jews groaned; their delivery by flight and a passage through the Red Sea; the history of the establishment of their very peculiar law, and many remarkable transactions; concluding with the building of the Tabernacle, or place appropriated to the service of the Divinity. This book comprises the history of 145 years, from the death of Joseph till the building of the Tabernacle. The Hebrews call it *Vaelle Shemoth*—that is, in English, *These are the names*, which are the words with which the book begins.

The third book of Moses is called *Leviticus*, because it contains the laws which God commanded should be observed by those of the tribe of *Levi* who ministered at the altar. It treats at large of all the functions of the Levites; of the ceremonial of religion; of the different sorts of sacrifices; of the distinction of clean and unclean beasts; of the different festivals; and of the year of jubilee, or continued holiday. It likewise presents us with an account of what happened to the Jews during the space of one month and a-half—that is, from the time the Tabernacle was erected—which was the first day of the first month of the second year after the Israelites came out of Egypt—till the second month of the same year, when God commanded the people to be numbered. The Hebrews call this book *Vayitro*—that is, *And he called*, these being its first words; they call it also the *Law of the Priests*.

In the fourth book, which we call *Numbers*, Moses numbers the Israelites, and that, too, in the beginning of the book, which shows whence it had its name. The Hebrews call it *Vayedaber*—that is, *And he spake*. This book contains the history of all that passed from the second month of the second year after the Israelites came out of Egypt, till the beginning of the eleventh month of the fortieth year—that is, it contains the history of thirty-nine years, or thereabouts. In it we have also the history of the prophet Balaam, whom the king of the Midianites brought to curse the people of God, and who, on the contrary, heaped blessings upon the Israelites, and foretold the coming of the Messiah. It particularly mentions, also, the two-and-forty encampments of the Israelites in the wilderness.

The fifth book is called *Deuteronomy*, a Greek term, which signifies *The second law*, or rather, *The repetition of the law*, because it does not contain a law different from that which was given on Mount Sinai; but it re-

peats the same law, for the sake of the children of those who had received it there, and had since died in the wilderness. The Hebrews call it *Elle-haddebarim*—that is, *These are the words*. Deuteronomy begins with a short account of what had passed in the wilderness, and then Moses repeats what he had before commanded in Exodus, Leviticus, and Numbers, and admonishes the people to be faithful in keeping the commandments of God. After this he relates what had happened from the beginning of the eleventh month to the seventh day of the twelfth month of the same year, which was the fortieth after their leaving Egypt. The discourse which is at the beginning of this book was made to the people by Moses on the first day of the eleventh month. According to the Jewish historian Josephus, Moses died on the first day of the twelfth; and the Israelites, as the Scripture says, mourned for him in the plains of Moab thirty days, and consequently during the whole of the twelfth month.

The Jews call the Pentateuch the *Law*, without doubt because the law of God, which Moses received on Mount Sinai, is the principal part of it; and it is as little to be doubted whether that great man was the writer of the Pentateuch. This is expressly declared both in Exodus and Deuteronomy. But as an account of the death of Moses is given in the last eight verses of this book, it is therefore thought that these verses were added either by Joshua or Ezra. The opinion of Josephus concerning them is very singular: he assumes that Moses, finding his death approaching, and being willing to prevent an error into which the veneration the people had for him might cause the Jews to fall, wrote his account himself; without which the Jews would probably have supposed that God had taken him away, like the patriarch Noah.

After the death of Moses, Joshua, by Divine command, took upon himself the conducting of the Hebrew people, and succeeded Moses, to whom he had been a faithful servant, and by whom he had been instructed in what he ought to do. It is uncertain whether the book which contains the history of this successor of Moses be called *Joshua*, from the subject of it, or from his having been the writer of it. But it is certain that it contains an account of what passed from the death of Moses to that of Joshua. Nevertheless, there are several things in it which did not come to pass till after the death of this great man, and which, consequently, could not have been written by him. The common opinion as to the length of time it contains is, that Joshua discharged his office only for seventeen years, and that therefore this book contains no more than the history of that number of years.

After the death of Joshua, the Israelites were governed by magistrates, who ruled under the general designation of *Judges*; and the book which contains the history of these rulers is called the *Book of Judges*. This history begins with the death of Joshua, and reaches to that of Samson. We here see the people of God often enslaved in punishment of their crimes, and often wonderfully delivered from slavery. Towards the end of it, we have some instances of this people's inclination to idolatry, and of the corruption of their manners, even before they had been brought into slavery. Such are the histories of Micah, and of the Benjaminites who abused the Levite's wife. This book contains the history of about three hundred years.

During the time of the government of Judges, there was a great famine in the land of Israel, which forced Elimelech, a native of Bethlehem, to retire into the land of Moab, with his wife Naomi and two children. Elimelech died there, as also his two sons, who had married two Moabitish women, one of whom was named Ruth. Naomi, after the death of her husband and her children, returned to Bethlehem, accompanied by Ruth, her daughter-in-law, who was there married to Boaz, Elimelech's near relation, and the heir to his estate. The book which contains this history is called the *Book of Ruth*. The beginning of it shows that it happened in the time of the Judges, but under which of them is not

certainly known: some place it in the time of Shamgar, or of Deborah. As to the writer of this book, some think that the books of Judges and Ruth were both written by Samuel; others attribute them to Hzekiah, and others to Ezra. The Jews place the book of Ruth among the five books which they usually read on all the festivals in the year. These five books are, the Song of Songs, Ruth, the Lamentations of Jeremiah, Ecclesiastes, and the book of Esther. In the Bibles used by the Jews they are printed or written apart by themselves, and are bound up together.

The four books following Ruth are called by the Greeks, and also in some Latin Bibles, the *History of the Reigns*. Others call them all the *Books of Kings*, because they give an account of the establishment of the monarchy, and of the succession of the kings, who reigned over the whole kingdom at first, and over the kingdoms of Judah and Israel after its division. At the beginning of these books is the history of the prophet Samuel, which gives light to that of the kings. The Jews call the first two of these books the *Books of Samuel*; perhaps because they contain the history of the two kings who were both anointed by Samuel, and because what is said of Saul in the *first*, and of David in the *second*, proves the truth of Samuel's prophecies. They give the name of the *Books of Kings* only to the other two, which in the Latin and French Bibles are called the *third and fourth Books of Kings*.

The *first Book of Kings*, or the *first of Samuel*, contains the history of the high-priest Eli, of his successor Samuel, and of Saul, and extends over a period of nearly eighty years.

The *second* contains the reign of David, which is the history of about forty years. It is commonly believed that Samuel, Nathan, and Gad, were the writers of these two books; and indeed they are called, in the end of the first book of *Chronicles*, *David's historians*.

The *third*, or, according to the Hebrews, the *first Book of Kings*, begins with a relation of the manner in which Solomon came to the throne, and contains the whole of his reign. After that, an account follows of the division of the kingdom, and the history of four kings of Judah and eight kings of Israel. All these reigns, including that of Solomon, which occupies the first forty years, comprise the space of 126 years.

The *fourth* of these books contains the history of sixteen kings of Judah and twelve kings of Israel; and embraces a period of three hundred years. It likewise gives an account of the prophets who lived during this time. It is quite uncertain who were the writers of the two last-mentioned books. They are by some attributed to Jeremiah or Ezra, but no very convincing proofs have been adduced in support of this opinion. It is evident, indeed, that these books form a varied collection of several particular histories.

The name of *Paralipomena*, which in Greek signifies the *history of things omitted*, is given to the two books which follow those of the *Kings*. These form, in fact, a supplement, containing what had been omitted in the *Pentateuch*, and the books of *Joshua*, *Judges*, and *Kings*; or rather they contain a fuller description of some things which had been therein only briefly related. Some give them the name of *Chronicles*, because they are very exact in mentioning the time when every transaction happened. We divide them into two books, as do also the Jews, who call them *Dibers Hayamin*—that is, a *Historical Journal*, the matters of which they treat having been taken from the Journals of the Kings. In the original language, however, the word *days* often signifies *years*, and in this sense we may understand the term to signify properly *Annals*. The generally received opinion is, that Ezra was the compiler of these. In the *first* book, he begins with a succinct historical abridgment, from the creation of Adam to the return of the Jews from their captivity; and then he resumes the history of David, and carries it on to the consecration of Solomon—that is, down to the year before Christ 1015. The history contained in the *second* book reaches down to the year before Christ 536, when, upon the

expiration of the seventy years of the captivity, Cyrus gave the Jews leave to return to their own country.

Ezra wrote the history of the return of the Jews from the captivity of Babylon into Judea. It is the history of about eighty-two years, from the year of the world 3468, when Cyrus became master of the Eastern Empire by the death of his father Cambyses in Persia, and his father-in-law Cyaxeres in Media, to the year 3550, which was the twentieth year of the reign of Artaxerxes, surnamed Longimanus. This book bears the name of Ezra, who was the writer of it.

The next book is a continuation of that of Ezra, and therefore it is by some called the *second book of Ezra*. It was Nehemiah, however, whose name it also bears, who wrote it, as is said, by the advice of Ezra. It contains the account of the re-establishment of Jerusalem, and of the Temple, and the worship of God. It is believed by some commentators to embrace the history of about thirty-one years; but its chronology is, on the whole, exceedingly uncertain.

After this general history of the Jews, follow two histories of particular persons—namely, *Esther* and *Job*. The first contains the account of a miraculous deliverance of the Jews, which was accomplished by means of the heroine named Esther. The history of Job is not only a narration of his actions, but contains also the entire discourses which this pious man had with his wife and his friends, and is indeed one of the most eloquent and poetic books in the Holy Scriptures. It is uncertain who was the author.

Next to the *historical* books of Scripture follow those of a moral nature. The first of these is the book of *Psalms*, which are likewise in some measure historical; for they recite the miracles which God had wrought, and contain, as it were, an abridgment of all that had been done for the Israelites, and that had happened to them. The Hebrews call them the *Book of Praises*, by which they mean, *of the praises of God*. The word *psalm* is Greek, and properly signifies the sound of a stringed instrument of music. The Hebrews sung the psalms with different instruments. We make but one book of them all, but the Hebrews divide them into five parts, which all end with the words *Amen, Amen*. Though the Psalms bear the name of David, yet they were not all composed by him: some of them are more ancient, and others are of a later date than his time; some of them being ascribed to Moses, Samuel, and Ezra. Speaking of the dedication of the second Temple, Prideaux says, 'In this dedication, the 146th, the 147th, and the 148th Psalms, seem to have been sung; for in the Septuagint versions they are styled the *Psalms of Haggai and Zechariah*, as if they had been composed by them for this occasion; and this, no doubt, was from some ancient tradition; but in the original Hebrew, these Psalms have no such title prefixed to them, neither have they any other to contradict it.' It is not probable, however, that all those whose names they bear were the actual authors of them: it is more likely that these are only the names of those to whom they were first given to sing.

After the Psalms are the *Proverbs*, which are a collection of moral sentences, of which Solomon was the writer. This name is given them by the Greeks, but the Hebrews call them *Misle*—that is, *Parables*, or *Comparisons*; and the word may also signify *Sentences*, or *Maxims*. It is a collection of precepts, proper for every age and every condition of life.

The book which follows is also a *moral* one, and was likewise composed by Solomon. The Greeks call it *Ecclesiastes*, which answers to the name of *Kohaleth*, which it bears in the Hebrew. Both these words signify in our language a *preacher*, or *one who speaks in an assembly*. In this book is given an admirable picture of the vanity of worldly expectations.

Among the *moral* books is also reckoned the *Song of Songs*—that is to say, according to the Hebrew manner of speaking, a *most excellent song*. It is an inspired production of Solomon, in the allegorical form of an *epithalamium*, or nuptial song significant of the mar-

riage and fellowship between Christ and his people: 'Its majestic style,' says Brown, 'its power on men's consciences to promote holiness and purity, the harmony of its language with that of Christ's parables, and of the book of Revelation; the sincerity of the bride in acknowledging her faults, and, in fine, its general reception by the Jewish and Christian church, sufficiently prove its authenticity.'

In regard to the Prophets, it may be observed that all the Old Testament is considered to be in substance one continued prophecy of the coming of a Messiah; so that all the books of which it consists are understood to be in some sense *prophetical*. But this name is more especially given to those books which were written by persons who had a clearer knowledge of futurity, who forewarned both kings and people of what would happen to them, and who at the same time pointed out what the Messiah was to accomplish, whom they who are acknowledged to have been prophets had always in view; and this is what ought most especially to be taken notice of in their writings.

The prophecies bear the names of those to whom they belong. Some learned men are of opinion that the Prophets made abridgments of the discourses which they had written, and fixed them up at the gates of the Temple, that all the people might read them; and that after this the ministers of the Temple might take them away, and place them among the archives, which is the reason why we have not the Prophecies in the order in which they were written. But the interpreters of Scripture have long since laboured to restore that order according to the course of their history.

The works of the Prophets are divided into two parts, the first of which contains the *Greater*, and the second the *Lesser Prophets*. This distinction of course does not apply to all to the persons of the prophets, but only to the bulk of their works. The *Greater Prophets* are Isaiah, Ezekiel, Daniel, and Jeremiah. The *Lamentations* of Jeremiah make a separate book by themselves, containing that prophet's descriptions of the destruction of the city of Jerusalem and of the captivity of the Jewish people. The *Lesser Prophets* are Hosea, Joel, Amos, Obadiah, Jonah, Micah, Nahum, Habakkuk, Zephaniah, Haggai, Zechariah, and Malachi. Their prophecies were formerly contained in a single volume, which the Hebrews call *Theresezer*, which means *Twelve*, or the *Book of the Twelve*.

The dates of many of the prophecies are uncertain, but the earliest of them was in the days of Uzziah, king of Judah, and Jeroboam the Second, his contemporary, king of Israel, about two hundred years before the captivity, and not long after Joash had slain Zechariah, the son of Jehoiada, in the court of the Temple. Hosea was the first of the writing prophets; and Joel, Amos, and Obadiah, it appears, promulgated their prophecies about the same time.

Isaiah began his remarkable prophecies a short time afterwards; but his book is placed first, because it is the largest of them all, and is more explicit respecting the advent of Christ than any of the others. The language of this eminent writer is exceedingly sublime and affecting; so much so, that it has never been equalled by any profane poet either in ancient or modern times. It is impossible to read some of the chapters without being struck by the force of the prophetic allusions to the character and sufferings of the Messiah; and in consequence of these prevailing characteristics, the author is ordinarily styled the *Evangelical Prophet*, and by some of the ancients, a *Fifth Evangelist*. The Jews say that the spirit of prophecy continued forty years during the second Temple; and Malachi they call the Seal of Prophecy, because in him the succession or series of prophets broke off, and came to a period. The book of Malachi, therefore, appropriately closes the sacred record of the Old Testament.

By referring to our historical sketch of the Jewish people (No. 55), it will be observed that the glory of Israel vanished at the period of the conquest and captivity of the nation, about six hundred years before

Christ. As a consequence, though not an immediate one, the inspired writings of the Old Testament were concluded soon after this event, or probably four hundred years before the coming of the Messiah. Thus a period of from four to five centuries elapsed from the time when Malachi concluded his prophetic enunciations, till that in which the Evangelists penned the books descriptive of Christ's life and ministrations.

## NEW TESTAMENT.

The second and lesser division of the Bible, as has been said, relates entirely to the Christian religion, or the fulfilment of that which was predicted and prefigured in the more ancient department of the work. This division of the Sacred Scriptures is generally styled the *New Testament*, or that which has been a later revelation and bequest; that portion of it which relates to the history of the life of Christ is called the *Gospel*, and by some the *Evangel*, both these words having the same meaning, and implying *good news*, or *glad tidings*, from the circumstance that the narratives contain an account of things which are to benefit mankind.

The New Testament, like the Old, is a compilation of books written by different inspired individuals, and all put together in a manner so as to exhibit a regular account of the birth, actions, and death of Christ—the doctrines he promulgated—and the prophecies regarding the future state of the church which he founded. The historical books are the four *Gospels* and the *Acts of the Apostles*, all these being of the character of narratives of events; the doctrinal are the Epistles of Paul, and some others; the prophetic book is the last, and is called the *Revelations* or *Apocalypse* of *St John*, having been written by that apostle while he was in exile in the island of Patmos.

The four Evangelists, or writers, are Matthew, Mark, Luke, and John; these having, as is generally believed, been companions of Christ during his ministrations, and therefore personally acquainted with his life and character. Each of the four books is principally a repetition of the history of Christ, yet they all possess a difference of style, and each mentions some circumstances omitted by the others, so that the whole is essential in making up a complete life of the Messiah. These distinctions in the tone of the narratives, and other peculiarities, are always considered as strong circumstantial evidence in proof of their authenticity, and of there having been no collusion on the part of the writers. But indeed the events they record are detailed in so exceedingly simple and unaffected a manner, that it is impossible to suppose that they were written with a view to impose on the credulity of mankind. The veracity and actual belief of the Evangelists themselves are placed beyond a doubt.

The first book is written by Matthew, who was by birth a Jew, and exercised the profession of a publican—that is, a collector of the public tax or assessment imposed upon the Jewish people by their conquerors the Romans. Matthew, who was also called by the name of Levi, was one of the twelve apostles of Christ, and he is said to have written his narrative from thirty to forty years after the departure of his Master from the earth. Many of the ancients say that he wrote it in the Hebrew or Syriac language; but it is more probable that there were two originals—one in Hebrew, and the other in Greek, the former written A. D. 37 or 38, and the latter A. D. 61; and that these were respectively designed for the Hebrew and Gentile nations.

With regard to Mark, the writer of the second Gospel, it may be observed that although Mark or Marcus was a common Roman name, there is reason to believe that this Evangelist was a Jew, who had changed his original appellation on being converted to the faith of Christ. Jerome says, that after the writing of this Gospel, he went into Egypt, and was the first that preached the Gospel at Alexandria, where he founded a church, to which he offered an example of holy living.

The Gospel of St Mark is much shorter than that of Matthew, not giving so full an account of Christ's ser-

mons as that did, but insisting chiefly on his miracles ; and in regard to these also it is very much a repetition of what we have in Matthew, many remarkable circumstances being added to the incidents there related, but not many new matters. There is a tradition that it was first written in Latin, because it was written at Rome; but this is generally thought to be without foundation, and that it was written in Greek, as was St Paul's Epistle to the Romans, the Greek being the more universal language. The Gospel of Mark was written at a somewhat later period than that of Matthew.

Luke, the name of the third Evangelist, is considered by some to be a contraction of *Lucius*; and he is said by St Jerome to have been born at Antioch. Some think that he was the only one of all the penmen of the Scriptures that was not of the Israelites; that he was a Jewish proselyte, and was converted to Christianity by the ministry of St Paul at Antioch; and that, after the coming of Paul into Macedonia, Luke was his constant companion. He had employed himself in the study and practice of physic; and hence Paul calls him *Luke the beloved Physician*. It is deemed probable that Luke wrote both his gospel and his narrative of the *Acts of the Apostles* at Rome, when he was there a prisoner with Paul, *preaching in his own hired house*—circumstances alluded to at the conclusion of the latter work. If this be the case, Luke's Gospel may be dated about thirty years after Christ's departure, or A.D. 63. Jerome says that St Luke died when he was eighty-four years of age, and that he was never married. Dr Cave observes, that 'his way and manner of writing are accurate and exact, his style polite and elegant, sublime and lofty, yet perspicuous; and that he expresses himself in a vein of purer Greek than is to be found in the other writers of this holy history.' Thus he relates several things more copiously than the other Evangelists, and thus he especially treats of those things which relate to the priestly office of Christ.

The fourth Evangelist, John, was one of the sons of Zebedee, a fisherman of Galilee, the brother of James, one of the Twelve Apostles, and distinguished by the honourable appellation of *that disciple whom Jesus loved*. The ancients tell us that John lived longest of all the Apostles, and was the only one of them that died a natural death, all the rest suffering martyrdom. It is now established that he wrote his Gospel about the year 97 or 98, when he was of an extremely old age. And it is believed, on good authority, that he was prevailed upon to undertake this important task by the solicitations of the Christian teachers, in order to counteract the mischievous effects produced by the doctrines of a sect, or rather of a multitude of sects, who were distinguished by the general denomination of Gnostics, and whose tenets were openly taught by Cerinthus before the publication of this Gospel. In a work like the present it would be entirely out of place to enter into a minute account of the tenets of the Gnostics; we may merely mention that the fundamental principle of their system was the inherent and incorrigible depravity of matter. In accordance with this principle, they made a complete separation between spiritual and material objects; maintaining that the Supreme Being merely presided over the spirits who had emanated from himself; and that an inferior being created the world, and bestowed existence upon the different grades of its inhabitants. They further held that mankind were kept under the thralldom of matter, but that a glorious messenger was to be sent, by the compassion of the Supreme Being, for the purpose of effecting their deliverance. The Christian Gnostics believed that Christ was this messenger. In opposition to this system John clearly teaches, that the Creator of the world, and the Saviour of the human race, is one and the same person, and declares in the plainest language that this person is Christ.

After the Gospel, or History of Jesus Christ, follows the history of what passed after his ascension, and was transacted by the Apostles. The book, therefore, which contains this history is called the *Acts of the Apostles*.

It is a history of the rising church for about the space of thirty years. It was written, as has been already observed, by St Luke the Evangelist, when he was with St Paul at Rome, during his imprisonment there. In the end of the book he mentions particularly his being with Paul in his dangerous voyage to Rome, when he was carried thither a prisoner; and it is evident that he was with him when, from his prison there, Paul wrote his epistles to the Colossians and Philemon, for in both of these Luke is named by him.

Next to this come the *Epistles of St Paul*, which are fourteen in number: one to the Romans; two to the Corinthians; one to the Galatians; one to the Ephesians; one to the Philippians; one to the Colossians; two to the Thessalonians; two to Timothy; one to Titus; one to Philemon; and one to the Hebrews. They contain that part of ecclesiastical history which immediately follows after what is related in the Acts. The principal matter contained in them is the establishment or confirmation of the doctrine which Jesus Christ taught his disciples. According as the difficulties which raised disputes among the Christians, or the heresies which sprang up in the church from the first age of it, required, St Paul in these epistles clears up and proves all matters of faith, and gives excellent rules for morality. His Epistles may be considered as a commentary on the four books of the Gospel.

The Epistle to the *Romans* is placed first, not because of the priority of its date, but on account of its superlative excellence, it being one of the longest and fullest of all, and perhaps also on account of the dignity of the place to which it is addressed. It is gathered from some passages in the Epistle, that it was written in the year of Christ 56, from Corinth, while Paul made a short stay there on his way to Trossa. He was then going up to Jerusalem with the money that was given to the poor saints there; which is spoken of in the fifteenth chapter of the Epistle.

The two Epistles to the *Corinthians* were written about a year after that to the Romans—namely, A. D. 57; that to the *Galatians*, A. D. 56; to the *Ephesians*, A. D. 61; to the *Philippians*, A. D. 62; to the *Colossians*, A. D. 62; two to the *Thessalonians*, A. D. 51 and 52; the first to *Timothy*, A. D. 64; the second to *Timothy*, A. D. 66; to *Titus*, A. D. 65; to *Philemon*, A. D. 62; and that to the *Hebrews*, A. D. 62. From which chronology it appears that the Epistles of St Paul are placed in the New Testament rather according to the dignity of the cities to which they were sent, than according to the order of time in which they were written; for the Epistles to the Thessalonians were those he wrote first, though that to the Romans is placed before them. Interpreters are agreed that the last Epistle which he wrote was the second to Timothy.

St Paul wrote to the churches of some particular places, or to some particular persons; but the other Epistles which follow his are called *Catholic* (that is, universal), because, with the exception of the second and third of St John, they were not addressed to any particular church or individual, as his were, but to the whole Christian Church in general. These Epistles are—one of St James; two of St Peter; three of St John; and one of St Jude. The date of most of these Epistles is extremely uncertain, but the most generally-received chronology of them is as follows:—That of St James, A. D. 61; of St Peter, A. D. 66 and 67; of St John, A. D. 80 and 90; of St Jude, A. D. 66.

It has sometimes occurred to the minds of well-disposed persons, that it would have been better for Christianity had there never been any other record of its origin and doctrines than the writings of Matthew, Mark, Luke, and John. But however plain and satisfactory the histories of these Evangelists may be, and however little they admit of controversy, it may, on the other hand, be observed, that the strong arguments and illustrations brought forward in the Epistles by Paul and others, were necessary, in order to combat the sophistry of the Greeks and the self-sufficient philo- sophies of other nations. Paul, the chief of the Epistle

writers, who became a Christian by conversion, after Christ had departed from the earth, is the great champion of the faith, and exposes, in strong and perspicuous language, the hidden depravities of the human heart; so that, where the affecting discourses and sufferings of the Messiah fail to convert and to convince, the reasoning of this great writer is calculated to silence and subdue those who stubbornly resist the benignant influence of the Christian faith.

Such, then, were the various books written to convey to posterity a faithful account of Christ's life and mission, and consequently of the religion which it was his purpose to institute. It will have been observed that the whole were inscribed within the first century, and gradually accumulated in the hands of the primitive church, as an imperishable basis on which the faith of Christians should be founded.

#### AUTHENTICITY OF THE SCRIPTURES—APOCRYPHA.

With respect to the authenticity of both the Old and New Testament books, as generally received, we of course look to the estimation in which they were respectively held by those with whom they had been deposited, and who unquestionably possessed the best evidences of their credibility. The Jews, as is well known, were most scrupulous in preserving entire the works of their inspired writers, and in preventing the intrusion of literal errors into the copies which were from time to time transcribed. Of the fidelity of the original text, there cannot, we think, be any reasonable doubt; and although there are what are called various readings, these are of an exceedingly unimportant character. Referring to this subject, it is said by the learned Dr Adam Clarke, 'that all the omissions of the ancient manuscripts put together, would not countenance the omission of any essential doctrine of the Gospel, relative to faith or morals; and all the additions countenanced by the whole mass of manuscripts already collated, do not introduce a single point essential either to faith and morals, beyond what may be found in the Complutensian or Elsevir editions.' Among other means adopted by the Jews to preserve the integrity of the Scriptures, was that of noting and recording the exact number of words, verses, points, and accents, in each book. The duty of doing so was the province of the Jewish doctors or learned men, called Masorites. By these acute grammarians, all the verses of each book and of each section were numbered, and the amount placed at the end of each in numerical letters, or in some symbolical word formed out of them; the middle verse of each book was also marked, and even the very letters were numbered; and all this was done to preserve the text from any alteration by either fraud or negligence. For instance, Bereshith, or Genesis, is marked as containing 1534 verses, and the middle one is at—'And by thy sword thou shalt live' (xxvii. 40). The lines are 4395; its columns are 45; and its chapters 50. The number of its words is 27,713, and its letters are 78,100. The Masoretic notes, or Masorah, as the work is called, contain also observations on the words and letters of the verses; for instance, how many verses end with the letter *samech*; how many there are in which the same word is repeated twice or thrice; and other remarks of a similar nature.

It seems now generally agreed upon that the Masorites of Tiberias, during the fourth century of the Christian era, were the inventors of the system of the *vowel-points and accents* in the Hebrew Bible; and although they multiplied them very unnecessarily, it must be allowed that they were an improvement of considerable importance (See BIBLIOGRAPHY). From the *points* we learn how the text was read in their time, as we know they were guided in affixing them by the mode of reading which then prevailed, and which they supposed to have been traditionally conveyed down from the sacred writers.

The respect which the Jews have uniformly paid to the sacred books has been almost allied to superstition.

They are directed to be written upon parchment, made from the skin of a clean animal, and to be tied together with strings of similar substance, or sewn with goats' hair which has been spun and prepared by a Jewess. It must be likewise a Jew that writes the Law, and they are extremely diligent and exact in it, because the least fault profanes the book. Every skin of parchment is to contain a certain number of columns, which are to be of a precise length and breadth, and to contain a certain number of words. They are to be written with the purest ink, and no word is to be written from memory; it must be first orally pronounced by the copyist. The name of God is directed to be written with the utmost attention and devotion, and the transcriber is to wash his pen before he inscribes it on the parchment. If there should chance to be a word with either a deficient or a redundant letter, or should any of the prosaic part of the Old Testament be written as verse, or *vice versa*, the manuscript is vitiated. No Hebrew manuscript with any illumination is, on any account, admitted into a synagogue, although private individuals are permitted to have them ornamented for their own use; but in the illustrations, the resemblance of any animal denounced by the Jews as unclean cannot be admitted. Among the modern Jews, the Book of Esther, in particular, is frequently decorated with rude figures of various kinds; but with respect to this book, it must be observed, that owing to its wanting the sacred name of God, it is not held in such repute for holiness as the other books are. The manuscripts for private use may be either upon parchment, vellum, or paper, and of various sizes. 'There is,' says Prideaux, 'in the church of St Dominic, in Bononia, a copy of the Hebrew Scriptures, kept with a great deal of care, which they pretend to be the original copy, written by Ezra himself; and therefore it is there valued at so high a rate, that great sums of money have been borrowed by the Bononians upon the pawn of it, and again repaid for its redemption. It is written in a very fair character, upon a sort of leather, and made up in a roll, according to the ancient manner; but its having the vowel-points annexed, and the writing being fresh and fair, without any decay, both these particulars prove the novelty of that copy.'

To open and shut up the roll or book of the Law, to hold it, and to raise and show it to the people, are three offices which are sold, and bring in a great deal of money. The skins on which the Law is written are fastened to two rollers, whose ends jut out at the sides beyond the skins, and are usually adorned with silver; and it is by them that they hold the book when they lift it up, and exhibit it to the congregation; because they are forbidden to touch the book itself with their hands. All who are in the synagogue kiss it, and they who are not near enough to reach it with their mouths, touch the silken cover of it, and then kiss their hands, and put the two fingers with which they touched it upon their eyes, which they think preserves the sight. They keep it in a cupboard, which supplies the place of the ark of the covenant, and they therefore call this cupboard *Aron*, which is the Hebrew name for the Ark; and this is always placed in the east end of the synagogue. He who presides chooses any one whom he pleases to read and explain the Scripture, which was a mark of distinction, as we see in the thirteenth chapter of the *Acts*, where we find the *rulers of the synagogue* desiring the apostles, when they were in the synagogues, to make a discourse to the people. Ordinarily speaking, a *priest* began, a *Levite* read on, and at last one of the people, whom the president chose, concluded. He who reads stands upright, and is not suffered so much as to lean against a wall. Before he begins, he says with a loud voice, *Bless ye God*, and the congregation answers, *Blessed be thou, O my God; blessed be thou for ever*; and when the lesson is ended, the book is rolled up, and wrapped in a piece of silk.

Certain books, collectively termed the *Apocrypha*, are sometimes included in the Bible, and of these it is necessary to give a brief account. The term *Apocrypha*

is Greek, signifying *hidden* or *concealed*, and is applied to those books whose origin is unknown, or the authenticity of which is either doubtful or absolutely denied. Some writers divide the sacred books into three classes—the canonical, the ecclesiastical, and the apocryphal. In the first they place those whose authority has never been questioned in the catholic or universal church; in the second, those which were not received at first, but which were nevertheless read in the public assemblies, as books that were useful, though they never placed them upon the same footing of authority as the former; and in the third, they placed the books which were of no authority, which could not be made to appear in public, but were kept *hidden*, and were therefore called *apocryphal*—that is, *concealed*, or such as could not be used in public. ‘Let us lay aside those books which have been called *apocryphal*,’ says St Augustine, ‘because their authors were not known to our fathers, who have, by a constant and certain succession, transmitted down to us the authority and truth of the Holy Scriptures. Though some things in these apocryphal books are true, yet as there are in them multitudes of others which are false, they are of no authority.’

The Apocrypha consists of *fourteen* books—namely, *First and Second Esdras*, *Tobit*, *Judith*, the rest of the chapters of the book of *Ezra*, the *Wisdom of Solomon*, *Ecclesiasticus*, *Baruch*, the *Song of the Three Holy Children*, the *History of Susanna*, the *Story of Bel and the Dragon*, the *Prayer of Manasse*, and the *First and Second Book of the Maccabees*. Biblical historians assert that these books were of a later composition than the other parts of Scripture, never existed in the proper Hebrew tongue, and were at no time received by the Jews as the writings of inspired men. It is the general belief of such Scripture critics as have made this subject their study, that the whole or greater part of the Apocrypha, was written between the time of the Babylonish captivity and the appearing of Christ, and by persons who had mixed with the Greeks and other foreign nations. The apocryphal books, it is observed, are never quoted in the New Testament, or by the Jewish writers Philo and Josephus; and by the early councils of the church they were formally excluded from the canon. On these points, however, as is well known, there exists a great difference of opinion—the Roman Catholic Church viewing the apocryphal books as canonical, and the Protestants entirely setting them aside, or using them only as works of ordinary edification, or for the light which they throw on the phraseology of Scripture and the history and manners of the East. With respect to the meaning and application of the term *canonical*, we here append a note.\*

\* The meaning of this term will be gathered from the following explanations in the *Encyclopædia Americana* (Conversations Lexicon):—‘The term *canon* (Greek) signifies a measure, rule, or standard; thence *canon* is used to denote the rule or standard of primitive Christianity. The same term is employed to designate the collection of books containing this rule—that is, the canonical books of the Holy Scriptures which the church acknowledges. The canon of the books of the Old Testament, as drawn up by the Jews in the fourth century before Christ, receives in this form equal respect among all Christians, because Christ and his apostles have expressly appealed to them, and pronounced them writings inspired by God. The apocryphal books of the Old Testament, whose canonical character the Jews did not acknowledge, the Eastern [or Greek] Church has never received; but the Western [or Roman] Church declared them canonical, in the African Council, about the end of the fourth century.’ What follows is said to be the explanation of a Catholic:—‘The Holy Scriptures are esteemed sacred by the Catholics, because the church has transmitted them from age to age as sacred, and illustrative of revelation, as far as any writings can be. The church has only declared what writings have been handed down as of Divine origin. The catalogue of these Holy Scriptures is the canon; the writings themselves are called canonical books. In this sense the Protestant Church has no canon: it rejects the authority of all traditions of the church. Hence, in order to be consistent, it must leave every Protestant, on free investigation, to decide what books he will regard as canonical. But the Bible, the pillar of the Protestant faith, is made up of separate canonical

books; and by pursuing such a course, the basis of the Protestant faith might be undermined. It has been agreed, therefore, however inconsistently, to adopt the New Testament canon of the Catholic Church. But in fixing the canon of the Old Testament, the decisions of the Catholic Church have been rejected; and contrary to the African Councils and the usage of the Romish Church, established by the Council of Trent, part of *Ezra*, also *Baruch*, *Tobit*, *Judith*, *Wisdom*, *Ecclesiasticus*, or *Jesus the Son of Sirach*, the *Two Books of Maccabees*, the *Song of the Three Youths in the Fiery Furnace*, described in *Daniel*, together with the last two chapters of this prophet, are thrown out as uncanonical or apocryphal. It is worthy of mention that a controversy on this subject broke off the negotiations for a union of the Catholic and Protestant Churches, which commenced in the beginning of the eighteenth century between Leibnitz, Molanus, and Bossuet.’ The above explanation is scarcely correct, as respects the Protestant idea of the canon of Scripture. The Church of England, for example, does not implicitly adopt the Roman Catholic canon: it founds its rule of faith on that which is believed to have been the canon in the earliest centuries of Christianity. ‘The Church of England, in determining the sense of the Bible, listens with respect to the voice of the most ancient fathers and doctors: and not only with respect, but even with submission, where that voice is all but unanimous.’—*Life of Jewel*. ‘The Council of Trent confirmed the decision of some previous councils, by which the books of the Apocrypha were declared to belong to the canon of the Old Testament; contrary to that of the Council of Laodicea, A. D. 364, which, by an express canon, sanctioned the catalogue of the sacred books as received by Protestants.’—*Josiah Conder’s View of all Religions*.

While attempts have been made to intrude uncanonical books into the authentic body of ancient Scripture, the New Testament has been exposed to similar vitiation. In the third and fourth centuries, there were gospels forged by divers sects, and published, one under the name of St Peter, another of St Thomas, another of St Philip, &c. They were never owned, however, by the church, nor was any credit given to them, as the learned Dr Whitby shows; and he gives this good reason why we should adhere to records written at or near the time of Christ—‘Because,’ says he, ‘whatever the pretences of tradition may be, it is not sufficient to preserve things with any certainty, as appears by experience. For whereas Christ said and did many memorable things which were not written, tradition has not preserved any one of them to us, but all is lost except what was written; and that therefore is what we must abide by.’

What has been said of the integrity of the text of the Old Testament, may be applied also to the New, in as far as it may be charged with corruptions in consequence of the negligence of transcribers. Though it must be admitted that the New Testament text, by being more frequently transcribed than the Old, became liable to a greater proportion of various readings, originating from the mistakes of the transcribers, yet this very circumstance was likewise a sure protection against wilful perversion or corruption; for in proportion as copies were multiplied, the difficulty of effecting a general corruption was increased. No such system as that of the Masorites was ever adopted to preserve the purity of the New Testament text; but we have it in our power to use various means for ascertaining what is the true reading of the text, without having recourse to such a plan as that of the Masorah; and Concordances, which are now brought to an uncommon degree of perfection, are of great use in preserving it from corruption. But the most satisfactory assurance that the books of the New Testament have been transmitted to the present times in their original purity, is to be found in the fact, that at a very early period a great variety of sects sprung up, and have continued to prevail, to a greater or less extent, in all ages of the church. This circumstance, although in many respects it is matter of regret, is yet attended with this signal advantage, that it rendered any material corruption of the oracles of Divine truth utterly impossible. The adherents of these various sects regarded all who differed from them in a single article of their religious creed with the utmost jealousy and

books; and by pursuing such a course, the basis of the Protestant faith might be undermined. It has been agreed, therefore, however inconsistently, to adopt the New Testament canon of the Catholic Church. But in fixing the canon of the Old Testament, the decisions of the Catholic Church have been rejected; and contrary to the African Councils and the usage of the Romish Church, established by the Council of Trent, part of *Ezra*, also *Baruch*, *Tobit*, *Judith*, *Wisdom*, *Ecclesiasticus*, or *Jesus the Son of Sirach*, the *Two Books of Maccabees*, the *Song of the Three Youths in the Fiery Furnace*, described in *Daniel*, together with the last two chapters of this prophet, are thrown out as uncanonical or apocryphal. It is worthy of mention that a controversy on this subject broke off the negotiations for a union of the Catholic and Protestant Churches, which commenced in the beginning of the eighteenth century between Leibnitz, Molanus, and Bossuet.’ The above explanation is scarcely correct, as respects the Protestant idea of the canon of Scripture. The Church of England, for example, does not implicitly adopt the Roman Catholic canon: it founds its rule of faith on that which is believed to have been the canon in the earliest centuries of Christianity. ‘The Church of England, in determining the sense of the Bible, listens with respect to the voice of the most ancient fathers and doctors: and not only with respect, but even with submission, where that voice is all but unanimous.’—*Life of Jewel*. ‘The Council of Trent confirmed the decision of some previous councils, by which the books of the Apocrypha were declared to belong to the canon of the Old Testament; contrary to that of the Council of Laodicea, A. D. 364, which, by an express canon, sanctioned the catalogue of the sacred books as received by Protestants.’—*Josiah Conder’s View of all Religions*.

strypcion, and with all that unseemly rancour and animosity which theological disputants, in all ages and countries, have been unfortunately too prone to indulge; and as they all pretended that their conflicting systems of belief were founded on the Scriptures, any vitiation of these sacred books, in order to accommodate them to a particular system, would at once have been detected and exposed. But no such detection or exposure has ever taken place. The conductors of theological controversies have indeed often disgraced both themselves and the cause they espoused, by ascribing vile motives and unworthy conduct to those whose tenets they were attempting to overthrow; but they have never ventured directly to accuse them of vitiating the Scriptures. The charge which they bring against their opponents is, not that they have altered or corrupted the Word of God, but that they have put an erroneous interpretation upon it. These sectarian jealousies and animosities, therefore, afford the strongest possible evidence that the books of the New Testament have come down to us pure and uncorrupted, since any attempt to alter their meaning, by the interpolation or omission of a single word, would most assuredly have been proclaimed to the world by a host of watchful and jealous opponents. It need only be added, that we have the consent of the Christian Church, in all ages and countries, to prove the fidelity of the New Testament Scriptures; and any variety occurring in the readings in modern times can arise only from heedlessness, or from motives of an improper kind.

With respect to the credibility, on general grounds, of the New Testament writers, and that the books are of that antiquity usually assigned to them, there cannot be any reasonable doubt; in other words, the writers wrote the books in perfect good faith, believing that what they penned was true, and the very books are those now before us in the New Testament. On these points an able divine remarks—'It must be esteemed a strong circumstance in favour of the antiquity of the New Testament, that on a subject in which the chances of detection are so numerous, and where we can scarcely advance a single step in the narrative without the possibility of betraying our time by some mistaken allusion, it stands distinguished from every later composition, in being able to bear the most minute and intimate comparison with the contemporary historians of that period. The argument derives great additional strength from viewing the New Testament, not as one single performance, but as a collection of several performances. It is the work of no less than eight different authors, who wrote without any appearance of concert, who published in different parts of the world, and whose writings possess every evidence, both internal and external, of being independent productions. Had only one author exhibited the same minute accuracy of allusion, it would have been esteemed a very strong evidence of his antiquity. But when we see so many authors exhibiting such a well-sustained and almost unexpected accuracy through the whole of their varied and distinct narratives, it seems difficult to avoid the conclusion, that they were either the eye-witnesses of their own history, or lived about the period of its accomplishment.'

A minor point in the history of the Bible now requires to be noticed. In the earliest times, the writings of the Old Testament were divided into books and short paragraphs equivalent to verses; but the division into chapters and verses in which they now appear was of a much later date. The separation of both the Old and New Testament books into chapters and verses is by some writers ascribed to Arlott, a Tuscan monk, or rather to Hugh Cardinalis, in the thirteenth century; while others allege that from the comments of Theophylact on the Gospel, this must have been effected two centuries earlier. The question is one of no great importance, and it is sufficient for the purposes of general knowledge to be informed that the division of the Scriptures into chapters and verses was the work of a Roman Catholic divine some time between the eleventh and thirteenth centuries.

## MODERN HISTORY OF THE BIBLE.

It will have been gathered from the preceding details that the books of the Old Testament were originally written in the Hebrew language, that being the tongue spoken by the ancient Jewish people; and that the books were inscribed on rolls or sheets of carefully-prepared parchment, and deposited only in the Temple, or preserved in the hands of the highest officers of religion. In this condition, and either in the Hebrew or Chaldaic tongue, they existed till translated into the language of the Greeks, under the name of the Septuagint. With respect to the exact period at which this translation was effected, history presents no uniform account. The translation is ordinarily assigned to seventy Jewish elders or interpreters—and hence the term *Septuagint*, which signifies seventy—who were employed by the Egyptian ruler Ptolemy Philadelphus, to furnish a copy of the Scriptures in Greek, a language with which he and his people were acquainted. Whether the narration of this circumstance, which is said to have occurred 277 years before the Christian era, be conformable with credible history, it is at least certain that the translation called the Septuagint was effected by Jews skilled in the Greek tongue at about the time specified, and it was afterwards held in high esteem by the Sanhedrim at Jerusalem. It may further be explained that it was this Greek version of the Scriptures which was always quoted by our Saviour and his apostles, whenever they made an appeal to the Sacred Writings. With the earliest organisation of the Christian Church may be said to have commenced a new era in the history of the Bible. The Old Testament books, whether in the form of Hebrew, Chaldaic, or Greek versions, were still cherished by the Hebrew priesthood, as they are at this day; but copies were likewise accessible to the early Christians, and by these pious apostles and disciples they were treasured as the prophetic testimony of God's eternal design for the salvation of mankind, in the grand event which had now actually occurred—the coming of Jesus Christ.

When the books of the New Testament were collected and authenticated by the early fathers and other members of the Christian Church, they were held in equal esteem with those of the Old, and carefully preserved along with them. Though still in detached manuscripts, they were generally in the Greek tongue; but during the first three centuries of our era, Latin, or the language of the Romans, came largely into use in literature, and in the same manner as the modern European languages in later times superseded the Latin, so did the Latin supersede the Greek. Augustine (born 354—died 430) mentions that previous to his time there existed a great number of Latin versions of the Scriptural writings. 'We know those who translated the Scriptures into Greek,' says he, 'and the number of them is not great; but the number of the Latin translators is infinite. When the faith came to be established, the first man who found a Greek copy, notwithstanding the little knowledge he had of the two languages, boldly undertook a translation of it.' From another passage of his writings it has been generally concluded that there was one particular version, called 'the Italian,' in higher estimation than the rest, and which was the authorised version of the Roman churches. However this may be, it is certain that the Latin Church required a version of the Scriptures formed directly from the Hebrew, as all the Latin translations in existence at that time had been taken from the SEVENTY. Jerome, who was the contemporary of Augustine, was in every respect best suited, of any of the learned men of that time, to the task of effecting a new translation, which he accordingly undertook. He began by correcting some books of the Old Testament in the Latin Bible, particularly the version of the Psalms, and marked those passages wherein any difference existed between the Latin version, the Greek of the Seventy, and the Hebrew original. He had early applied himself to the study of the Hebrew language,

and at different periods had the assistance of five Jewish teachers; he had access also to the works of Origen, who published what is called the *Hexapla*—that is, the Bible in six different languages. From these he must have derived considerable assistance in the work he undertook—that of translating into Latin all the books of the Old Testament, to which he added a corrected edition of the common version of the New.

The work thus ascribed to Jerome (or St Jerome, as he is ordinarily called) received the name of the *Vulgate*, and both by Christians and Jews has been considered a faithful translation. It was sanctioned by the Council of Trent, since which time corrected editions have been published under the authority of the Pope Sixtus V. and Clement VIII. By the Roman Catholic Church the *Vulgate* is held in the highest esteem, and is reckoned equivalent in value to the Scriptures in the original tongues.

This seems to us the most proper place to notice—what must be clear to every one's comprehension—that for the safe custody and verification of the Scriptures, from the period at which the New Testament books were collected, we are indebted to the church, or, to speak more plainly, that series of ecclesiastical functionaries whose history is extended from the apostolic times till the present. Until the Bible, therefore, was secured to the people by the greatest of all mechanical applications, the art of printing, and in that respect placed beyond the reach of private interpolation or error, its safety, as a record, was dependent on the care and affection of the church; and for the faithful performance of that important service, no one surely will refuse a due meed of thankfulness and praise. From motives no doubt conscientious, many who have now the Bible in their hands may consider the church a valueless institution; but to this incorporation are they unquestionably indebted for preserving the Scriptures through ages of persecution and civil uproar. From the era of Augustine and Jerome, when copies of the sacred books came into considerably greater request by the scattered branches of the church, transcripts were effected by priests, and latterly by monks, with a diligence and accuracy which demand our utmost esteem and approbation. In the cells of monasteries, surrounded by hordes of barbarous nobles and their serfs, learning found refuge from oppression; and there, in the darkest ages of European history, were humble and pious ecclesiastics engaged, certainly from no worldly consideration, in penning copy after copy of the Sacred Writings, and bequeathing them as memorials of their industry to future and more fortunate generations.

Both before and after the application of printing to multiply copies of the Bible, translations, either direct from the original tongues, or from the Greek versions, were effected by almost every people to whom Christianity was introduced. Thus copies of the Scriptures in Arabic, Persian, Slavonic, and other tongues, were produced. One of the most ancient of these is that translated for the use of the Armenian Christians in the fifth or sixth century.\* Portions of the Scriptures are

\* For the more commodious comparison of different versions, many of them have been sometimes joined together. In his eightfold Bible, Origen placed, in different columns, a Hebrew copy, both in Hebrew and in Greek characters, with six different Greek versions. Elias Hutter, a German, about the sixteenth century, published the New Testament in twelve languages—namely, in Greek, Hebrew, Syriac, Latin, Italian, Spanish, French, German, Bohemian, English, Danish, Polish; and the whole Bible in Hebrew, Chaldaic, Greek, Latin, German, and a varied version. But the most esteemed collections are those in which the originals and ancient translations are conjoined, such as the Complutensian Bible, by Cardinal Ximenes, a Spaniard; the King of Spain's Bible, directed by Montanus, &c.; the Paris Bible, by Michael Jay, a French gentleman, in ten large folio volumes, copies of which were published in Holland under the name [or sanction] of Pope Alexander VII.; and that of Brian Walton, afterwards bishop of Chester. This last is the most regular and valuable: it contains the Hebrew and Greek originals, with Montanus's interlinear version; the Chaldee paraphrase, the Septuagint, the Samaritan Pentateuch, the Syriac

understood to have been translated into Anglo-Saxon, for use in the first British churches, as early as the sixth or seventh centuries; and the whole Bible was translated by Bede, an eminent Romish ecclesiastic, in the beginning of the eighth century. The first English Bible we read of was that translated by Wickliffe, one of the earliest English reformers, about the year 1360, but never printed. The part of the English Bible first printed was the New Testament, translated by William Tindal, assisted by Miles Coverdale; it was printed abroad in 1526, but, giving offence to the church, was bought up and burnt. In 1532, Tindal and his associates finished the whole Bible except the Apocrypha, and printed it abroad; but while he was afterwards preparing for a second edition, he was taken up and burnt for heresy in Flanders. On Tindal's death, his work was carried on by Coverdale and John Rogers, superintendent of an English church in Germany, and the first martyr in the reign of Queen Mary, who translated the Apocrypha, and revised Tindal's translation, comparing it with the Hebrew, Greek, Latin, and German, and adding prefaces and notes from Luther's Bible. He dedicated the whole to Henry VIII. in 1537, under the borrowed name of Thomas Matthews; whence this has been usually called *Matthew's Bible*. It was printed at Hamburg, and license obtained for publishing it in England by the favour of Archbishop Cranmer and the Bishops Latimer and Shaxton. The first Bible printed by authority in England, and publicly set up in churches, was the same Tindal's version, revised, compared with the Hebrew, and in many places amended, by Miles Coverdale, afterwards bishop of Exeter, and examined after him by Archbishop Cranmer, who added a preface to it; whence this was called *Cranmer's Bible*. It was printed by Grafton, was of large size, and published in 1540; and, by a royal proclamation, every parish was obliged to set one of the copies in its church, under the penalty of forty shillings a month; yet, two years after, the bishops obtained its suppression by the king. It was restored under Edward VI., suppressed again under Queen Mary, and restored again in the first year of Queen Elizabeth, and a new edition of it given in 1562. Some English exiles at Geneva in Queen Mary's reign—namely, Coverdale, Goodman, Gilbie, Sampson, Cole, Whittingham, and Knox, effected a new translation, printed there in 1560—the New Testament having been printed in 1557—hence called the *Geneva Bible*, containing the variations of readings, marginal annotations, &c. on account of which it was much valued by the Puritan party in that and the following reigns. Archbishop Parker resolved on a new translation for the public use of the church, and engaged the bishops and other learned men to take each a share or portion. These being afterwards joined together, and printed with short annotations in 1568, in large folio, made what was afterwards called the *Great English Bible*, and commonly the *Bishop's Bible*. In 1589 it was also published in octavo, in a small, but fine black-letter; and here the chapters were divided into verses; but without any breaks for them, in which the method of the Geneva Bible was followed, which was the first English Bible where any distinction of verses was made. It was afterwards printed in large folio, with corrections, and several prolegomena, in 1572: this is called *Matthew Parker's Bible*. The initial letters of each translator's name were put at the end of his part. The archbishop oversaw, directed, examined, and finished the whole. This translation was used in the churches

and Arabic Bibles, the Persian Pentateuch and Gospels, the Ethiopic Psalms, Song of Solomon, and New Testament, with their respective Latin translations; together with the Latin *Vulgate*, and a large volume of various readings, to which is ordinarily joined *Castel's Heptaglot Lexicon*—all included in eight volumes folio.—*Brown's Dictionary of the Bible*. Biblical scholars are now greatly assisted in their studies by the publication of polyglott editions of the Bible, containing in parallel columns versions in various ancient and modern languages, The Greek word *polyglott* signifies 'many tongues.'

for forty years, though the Geneva Bible was more read in private houses, being printed above twenty times in as many years.\*

Various editions of the Bishop's Bible were printed at London in black-letter at the beginning of the seventeenth century; but notwithstanding the care that had been expended on it, the version was not very correct, and its language was often far from elegant. To amend these deficiencies, and to obtain a really excellent version, James I. ordered an entirely new translation, which is that now in common use throughout Great Britain. To effect this very important undertaking, forty-seven distinguished scholars were appointed, and divided into six classes. Ten at Westminster were to translate to the end of 2d Kings; eight at Cambridge were to finish the remaining historical books and the Hagiographa; at Oxford, seven were engaged on the Prophets, eight upon the four Gospels, the Acts of the Apostles, and the Apocalypse; the Apocryphal books were to be translated at Cambridge. Each individual translated all the books allotted to his class; the whole class then compared all the translations, and adopted the readings agreed on by the majority. The book, thus finished, was sent to each of the other classes. Three years were consumed in this arduous duty of translating and examining. Copies were then sent to London, one from each of the above-named places. Here a committee of six, one from each class, reviewed the whole, which was last of all revised by Dr Smith, and Dr Bilson, bishop of Winchester. Having received the approbation of the king, himself no mean scholar, it was printed in 1611. We are not informed by any writer, whether the translation was effected from Hebrew copies of the Old Testament or the Greek Septuagint, or whether any transcriptions of the original manuscripts were consulted;† but it is allowed by all persons competent to judge, that the version possesses extraordinary merit, and is the most perfect ever produced.

#### CHRISTIANITY—HISTORY OF THE CHURCH.

At the period of Christ's appearance on earth,† the land of Judea had sunk to the condition of a Roman province, and its people, the Jews, were in a condition not only of civil, but great moral degradation. Their religion, as appears from all history, had degenerated from its ancient and lofty character, and existed only as a system of empty external observances, in the hands of a priesthood to the last degree corrupt. The leaders of the people, and the chief priests, according to the account of Josephus, were persons of profligate manners, who had purchased their places by bribes, or by acts of iniquity, and who maintained their authority, in subordination to the Roman civil power, by flagitious crimes. The multitude, affected by the example of their superiors, were not less corrupted in morals; and in a general sense, it may be understood that the entire nation was in a state of lamentable disorder. To aggravate the distractions of the people, they were divided into a variety of sects, who, in proportion as they neglected the essentials of religious faith and practice, occupied themselves in disputes respecting matters of inferior concern. Of these sects, three in a great measure eclipsed the rest, both by the number of their adherents, and also by the weight and authority which they acquired: these were the Pharisees, the Sadducees, and the Essenes. The chief difference of opinion among

\* The most ancient manuscripts of the Bible, in the original Hebrew, are to be found among the Jews in Spain (or were so some years ago), but none of them is above seven or eight hundred years old: a manuscript in the Bodleian Library at Oxford is thought to be seven hundred years old; in the library of the Vatican at Rome there are manuscripts, we believe, of parts of the Old and New Testament which are of considerable antiquity. The first edition of the entire Hebrew Bible was printed at Soncino in 1489; and the Breve edition of 1494 was used by Luther in making his German translation.

† The term *Christ* is from the Greek, and signifies 'the Anointed'; *Messiah*, from the Hebrew, has the same meaning.

these leading sects regarded the interpretation to be put on the words in the Holy Scriptures; and none of them seemed to have the interests of true piety at heart. The best of the three was the Essenes, who discountenanced ostentation in religious offices, and inclined to lives of secluded meditation. While the Jews, then, were thus broken up into contending sects, and were apparently in a state of profound ignorance of the true principles of religion, Jesus Christ appeared amongst them, to execute his divine mission, which referred not only to them, but the whole human race. In the writings of the Evangelists we are furnished with so remarkably precise an account of the birth and public ministrations of Christ, as also of his death and passion, as to leave nothing to be said here on the subject; and we pass on to an enunciation of the principles which it was the object of his mission to accomplish, and a historical sketch of that universal society of believers, the church, which he empowered to work out his designs.

Supposing Christianity, or the religion of Christ, to be reducible to a single principle, it might be described as a universal truth adapted to all mankind, and of a divine, all-uniting power—a principle of love and universal brotherhood, without respect of nation, age, rank, colour of skin, or any other exterior circumstance; in short, a system of faith and practice for the whole human race. A religion to be so universally applicable should necessarily embrace no tenet or observance which required special localisation. Judaism required a periodic visitation to the Temple at Jerusalem; Mohammedanism requires the performance of pilgrimages to certain cities in Arabia, also attention to forms only suitable to the daily and seasonal influences of a warm climate; Hindooism enjoins constant ablutions in the Ganges, besides other local observances—all which mark these religions as but referable to certain nations and countries, and not compatible with modes of existence in all parts of the earth. Setting aside, for the present, all other considerations, Christianity, by including no obligation which could not be as well performed in one part of the globe as another, or as well in one age as another, is something very different from religions either temporary or local in their character. It is in this universal and eternal applicability, therefore, that we find one of the grandest features of the religion of Christ.

The promulgation of the principle of universal benevolence and love—the antagonism of every evil or violent emotion—was, whatever may be said of it, new to the Jewish people. True, they believed in one God, the Creator of all things, and so far had just views of the Source of religion; they also possessed the commandments of the Mosaic law; but when, on any occasion, did they view the Gentile nations, or foreigners, in any other light than as an inferior race of mankind, to whom their laws and usages had no sort of applicability? Practically, their religion narrowed the affections, while Christianity was all for widening them. 'The Greeks, besides developing the principle of the beautiful in their works of art,' (we quote from the article *CHRISTIANITY* in the *Encyclopædia Americana*), 'had laid the foundations of valuable sciences, applicable to the business of life. The Romans had established the principles of law and political administration, and proved their value by experience. These scattered elements of moral and intellectual cultivation, insufficient in their disunited state to bring about the true happiness and moral perfection of man, in his social and individual capacity, were refined, perfected, and combined, by Christianity, through the law of a pure benevolence, the highest aim of which is that of rendering men good and happy, like God, and which finds, in the idea of a kingdom of heaven upon earth, announced and realised by Christ, all the means of executing its design. His religion supplied what was wanting in these nations—a religious character to the science of Greece, moral elevation to the legislative spirit of Rome, liberty and light to the devotion of the Jews; and by inculcating the precept of universal

love of mankind, raised the narrow spirit of patriotism to the extended feeling of general philanthropy. Thus the endeavours of ancient times after moral perfection were directed and concentrated by Christianity, which supplied at the same time a motive for diffusing more widely that light and those advantages which mystery and the spirit of caste had formerly withheld from the multitude. It conveyed the highest ideas, the most important truths and principles, the purest laws of moral life, to all ranks; it proved the possibility of perfect virtue, through the example of its Founder; it laid the foundation for the peace of the world, through the doctrine of the reconciliation of men with God and with each other; and directing their minds and hearts towards Jesus, the Author and Finisher of their faith, the crucified, arisen, and glorified Mediator between heaven and earth, it taught them to discern the benevolent connection of the future life with the present.'

Systems of chronology differ with regard to the year of the crucifixion of the Saviour, some placing it in A. D. 30, and others in A. D. 33. In either case, as is known to the readers of the evangelical history, the apostles and disciples who had followed him while on earth, began, shortly after his departure, those ministrations which they were commissioned to execute by their divine Master, and which had for their object the dissemination of the Gospel in all parts of the world. It will be further recollected, that in consequence of the defection and death of the traitor Judas, the apostles were reduced to eleven in number—Peter, and Andrew his brother; James the son of Zebedee, and John his brother; Philip and Bartholomew; Thomas and Matthew; James the son of Alphaeus, and Jude his brother; lastly, Simon the Canaanite. Afterwards, they elected Matthias in place of Judas. The number, however, was again reduced to eleven, by the murder of James, the brother of John, by Herod (A. D. 44).

The first society or church established by the apostles was at Jerusalem; and from all that can be learned, it was on the most simple and unpretending scale, corresponding to the nature of the religion which they professed. One of Christ's most emphatic declarations had been that 'his kingdom was not of this world;' by which he signified that the Christian doctrines and graces referred exclusively to the mental affections, were a business of the heart, not of outward show or demonstration, and had in other respects no alliance with civil dominion. The humble but intrepid apostles, therefore, in the course of their preaching and teaching in Judea, and afterwards in other countries, took no part in any design to subvert temporal governments, or to bring them into contempt; neither did they seek to ally themselves with civil rulers, but confined themselves in all places to their proper functions of calling sinners to be converted to the faith of Jesus, comforting those who mourned, animating the piety of the dejected, and, in particular, assisting the poor and needy. Of the forms of Christian worship in this infant state of the church, little is known; and, indeed, it appears that some time elapsed before the converted, or at least the pupils to the apostolic teachers, forsook the forms enjoined in the old Judaic mode of worship. According to Mosheim, they 'held separate assemblies, in which they were instructed by the apostles and elders, prayed together, celebrated the Holy Supper in remembrance of Christ, of his death and sufferings, and the salvation offered to mankind through him; and at the conclusion of these meetings, they testified their mutual love, partly by their liberality to the poor, and partly by sober and friendly repasts, which thence were called *feasts of charity*. Among the virtues which distinguished the rising church in this its infancy, that of beneficence to the poor and needy shone in the first rank and with the brightest lustre. Having finished their work at Jerusalem, the apostles proceeded to other nations, and travelled over a great part of the known world, in a short time planting a vast number of churches among the Gentiles. Several of these are mentioned in the Sacred Writings, particularly in the

*Acts of the Apostles*, though these are undoubtedly but a small part of the churches which were founded, either by the apostles themselves or by their disciples under their immediate direction.'

It is not our design to enter into a formal detail of what constituted the various points of belief and religious practice in this early age of the church. It will be understood that there was at first no body of written evidence answering as a fountain of doctrine and precept, such as we now possess in the collected books of the New Testament; and that apostles, and those who were raised up to assist them in their holy cause, were accordingly thrown much more on their own resources, and more dependent on God's inspiring power to teach and direct, than required to be the case in more advanced times. To use the words of Mosheim—'Among the first professors of Christianity there were but few men of learning; few who had capacity enough to insinuate into the minds of a gross and ignorant multitude the knowledge of divine things. God, therefore, in his infinite wisdom, judged it necessary to raise up, in many churches, extraordinary teachers, who were to discourse in the public assemblies, upon the various points of the Christian doctrine, and to treat with the people, in the name of God, as guided by his direction, and clothed with his authority. Such were the *prophets* of the New Testament.—(Rom. xiii. 6; 1st Cor. xii. 28; xiv. 3–29; and Eph. iv. 11.)

Much as we desire to do so, it is impossible for us to pass over a circumstance in the history of these early times, which has led to centuries of discord; we allude to the early form of church government. We shall allow a place to Mosheim's explanations on this subject. 'Neither Christ himself, nor his holy apostles, have commanded anything clearly or expressly concerning the external form of the church, and the precise method according to which it should be governed. From this we may infer that the regulation of this was in some measure to be accommodated to the time, and left to the wisdom and prudence of the chief rulers, both of the state and of the church. If, however, it is true that the apostles acted by Divine inspiration, and in conformity with the commands of their blessed Master (and this no Christian can call in question), then it follows that that form of government which the primitive churches borrowed from that of Jerusalem, the first Christian assembly established by the apostles themselves, must be esteemed as of Divine institution. But from this it would be wrong to conclude that such a form is immutable, and ought to be invariably observed; for this a great variety of events may render impossible. In those early times, every Christian Church consisted of the *people*, their *leaders*, and the *ministers*, or *deacons*; and these, indeed, belong essentially to every religious society. The people were undoubtedly the first in authority; for the apostles showed, by their own example, that nothing of moment was to be carried on or determined without the consent of the assembly, and such a method of proceeding was both prudent and necessary in those critical times.

It was therefore the assembly of the people which chose their own rulers and teachers, or received them by a free and authoritative consent, when recommended by others. The same people rejected or confirmed by their suffrages the laws that were proposed by their rulers to the assembly, excommunicated profligate and unworthy members of the church, restored the penitent to their forfeited privileges, passed judgment upon the different subjects of controversy and dissension that arose in their community, examined and decided the disputes which happened between the elders and deacons, and, in a word, exercised all that authority which belongs to such as are invested with the sovereign power. The people, indeed, had in some measure purchased these privileges, by administering to the support of their rulers, ministers, and poor, and by offering large and generous contributions, when the safety or interests of the community rendered such contributions necessary. In these supplies, each one bore a part

proportioned to his circumstances; and the various gifts which were thus brought into the public assemblies were called *oblations*.

The rulers of the church were called either *presbyters* or *bishops*, which two titles are in the New Testament undoubtedly applied to the same order of men. These were persons of eminent gravity, and such as had distinguished themselves by their superior sanctity and merit. Their particular functions were not always the same; for while some of them confined their labours to the instruction of the people, others contributed in different ways to the edification of the church. Hence the distinction between *teaching* and *ruling presbyters* has been adopted by certain learned men. But if ever this distinction existed, which I neither affirm nor deny, it certainly did not continue long; since it is manifest that St Paul requires that all bishops or presbyters be qualified and ready to teach and instruct.

The church was undoubtedly provided from the beginning with inferior ministers or *deacons*. No society can be without its servants, and still less such societies as those of the first Christians were. And it appears not only probable, but evident, that the *young men*, who carried away the dead bodies of Ananias and Sapphira, were the subordinate ministers, or *deacons* of the Church of Jerusalem, who attended the apostles to execute their orders. All the other Christian churches followed the example of that of Jerusalem in whatever related to the choice and office of the deacons.

Such was the constitution of the Christian Church in its infancy, when its assemblies were neither numerous nor splendid. Three or four presbyters, men of remarkable piety and wisdom, ruled these small congregations in perfect harmony, nor did they stand in need of any president or superior to maintain concord and order where no dissensions were known. But the number of the presbyters and deacons increasing with that of the churches, and the sacred work of the ministry growing more painful and weighty by a number of additional duties, these new circumstances required new regulations. It was then judged necessary that one man of distinguished gravity and wisdom should preside in the council of presbyters, in order to distribute among his colleagues their several tasks, and to be a centre of union to the whole society. This person was at first styled the *angel* of the church to which he belonged, but was afterwards distinguished by the name of *bishop*, or *inspector*; a name borrowed from the Greek language, and expressing the principal part of the episcopal function, which was to inspect and superintend the affairs of the church. It is highly probable that the Church of Jerusalem, grown considerably numerous, and deprived of the ministry of the apostles, who were gone to instruct the other nations, was the first which chose a president or bishop. And it is no less probable that the other churches followed by degrees such a respectable example. . . . A bishop, during the first and second centuries, was a person who had the care of one Christian assembly, which at that time was, generally speaking, small enough to be contained in a private house. In this assembly he acted, not so much with the authority of a *master*, as with the zeal and diligence of a faithful *servant*. He instructed the people, performed the several parts of Divine worship, attended the sick, and inquired into the circumstances and supplies of the poor. He charged, indeed, the presbyters with the performance of those duties and services which the multiplicity of his engagements rendered it impossible for him to fulfil; but had not the power to decide or enact anything without the consent of the presbyters and people. And though the episcopal office was both laborious and singularly dangerous, yet its revenues were extremely small, since the church had no certain income, but depended on the gifts or oblations of the multitude, which were no doubt inconsiderable, and were, moreover, to be divided between the bishops, presbyters, deacons, and poor.

The power and jurisdiction of the bishops were not long confined to these narrow limits, but soon extended

themselves, and that by the following means:—The bishops who lived in the cities had, either by their own ministry, or that of their presbyters, erected new churches in the neighbouring towns and villages. These churches, continuing under the inspection and ministry of the bishops by whose labours and counsels they had been engaged to embrace the Gospel, grew imperceptibly into ecclesiastical provinces, which the Greeks afterwards called *dioceses*. But as the bishop of the city could not extend his labours and inspection to all these churches in the country and in the villages, he appointed certain suffragans or deputies to govern and to instruct these new societies; and they were distinguished by the title of *chorepiscopi*—that is, country bishops. This order held the middle rank between bishops and presbyters, being inferior to the former, and superior to the latter.

The churches in those early times were entirely independent; none of them subject to any foreign jurisdiction, but each one governed by its own rulers and its own laws. For though the churches founded by the apostles had this particular deference shown them, that they were consulted in difficult and doubtful cases, yet they had no juridical authority, no sort of supremacy over the others, nor the least right to enact laws for them. Nothing, on the contrary, is more evident than the perfect equality that reigned among the primitive churches; nor does there even appear in this first century the smallest trace of that association of provincial churches from which *councils* and *metropolitans* derive their origin. It was only in the second century that the custom of holding councils commenced in Greece, from whence it soon spread through the other provinces.

According to these explanations, it would appear that the earliest constitution of the church was exceedingly simple, being in a great measure a confederacy of separate and independent religious instructors; that it gradually assumed the external features of Presbyterianism (equality of rank, but mutual jurisdiction); and that finally, as Christianity spread, and the scattered societies of believers required the supervision and counsel of superiors, there arose a species of Episcopacy, or superintendency by apostolic bishops. According to others, the bishops exercised a superintendency from the first, the earliest being the apostles; and it is reasonable to suppose that some such superior directors, exercising an authority in a spirit of perfect love, must have been necessary for the sake of order and uniformity of doctrine; it is at the same time certain that, whether in the capacity of equals or superiors, the apostles and early bishops performed the office of ordinary teachers of religion. The commissioning of ministers of the gospel by ordination, or the symbol of laying on of hands, appears to have existed from the earliest ages of Christianity. The members of the church at Antioch, founded by Paul and Barnabas, were the first who received the name of *Christians*, having been previously called Nazarenes, by way of derision.

From about the conclusion of the first till the sixth century, there flourished a body of eminent men in connection with the church, whose functions may be said to have generally united those of a professor of divinity and ethics with the pastoral office. These are known in Church History by the title of *Fathers*. They were of two chief classes—Greek and Latin fathers—and were alike distinguished for their erudition. The most celebrated among the Greek fathers was Clement of Alexandria (beginning of the second century), who was the first who philosophised on Christianity; Origen, at one time a pupil of Clement, celebrated for his homilies and writings illustrative of the Scriptures; Eusebius, who wrote the first history of Christianity; Athanasius (296–373), bishop of Alexandria, and a man of invincible courage under persecutions, whose writings exerted a considerable influence on the Christian dogmas; and Chrysostom (344–407), an ascetic, the most admired of the ancient orators. The most distinguished among the Latin fathers were—Tertullian,

born about the middle of the second century, and a writer of great originality; Augustine (354-430), a man of persuasive eloquence, exalted piety, and a warm encourager of the monastic life; Ambrose (340-397), bishop of Milan, an eminent orator, and famed for his mild and humane character; and Jerome (331-420), one of the most learned writers and able expounders of the Scriptures, which, as formerly mentioned, he translated into the Latin tongue.

In the course of the second and third centuries, the history of the church is painfully disfigured by the assumption of dominant powers by bishops; the division of the clergy into subordinate ranks and offices; the increase of ceremonial observances, fasts, and festivals; and, above all, differences of opinion among Christians on matters of belief. One main cause of the variety of opinion might be traced to the collateral influence of the Grecian philosophies, particularly that of Plato. Many converts had been educated in these philosophies, and though Christianised, they still retained the subtle speculative notions implanted in their minds, as well as divers pagan usages. From disputing in the schools of Athens on questions in metaphysics, they betook themselves to controversies on the most abstruse points of theology. From controversy, the disputants naturally subsided into heresy and schism; and hence we find, that while the Christian Church was on all sides struggling against barbarous powers, it was itself torn by intestine division. In this general sketch, we can only mention that the leading sectaries at this period were the Manichæans, Hieracites, Sabellians, and Novatians; and in the fourth century the heresy of Arius broke out, and produced incalculable injury. Prior to this latter event, the external condition of the church underwent an entire change.

For nearly three hundred years after the death of Christ, the church, though gradually altering in internal organisation, doctrinal belief, and ritual observance, was still an independent spiritual community, reposing on the simple but glorious basis on which it had been placed by its Divine Author, and in which condition it may be said to have been invulnerable. The conversion of Constantine the Roman Emperor in 321 (See No. 57); at once altered the primitive state of the church. \* Before that important period, some churches had been liberally supported by the devotion and zeal of wealthy individuals; but yet the situation of the clergy was insecure and contemptible in the eyes of the pagan world. Afterwards they lived in princely splendour, honoured and esteemed as the first rank of men in the empire. Formerly, they had been sunk in the gloom of obscurity, but now they basked in the broad sunshine of honour, wealth, and imperial favour. To a person who contemplates the aspect of the Roman Empire in that age, a new world seems to appear. The system of polytheism and idol worship which, from time immemorial, had, by its pompous ceremonies and splendid festivals, commanded the veneration of mankind, fell into disrepute; and Christianity, which had so long been the object of universal contempt, and frequently of cruel persecution, at last triumphed over all opposition, and became the established religion of the masters of the world. The Roman Empire saw magnificent churches erected for the worship of the crucified God, whose name had been long despised, and the rites of the Christian religion celebrated with a pomp and solemnity equal, if not superior, to what had been displayed in the pagan temples. A total revolution was taking place in the texture of religious opinions and the combinations of human ideas. What a scene would this have appeared to a Christian of the apostolic age, or of that which immediately succeeded it! What would a Christian whose mind had been formed, whose religious ideas had been modelled, by the simple and disinterested maxims of primitive Christianity, think, on seeing the ministers of the humble and lowly Jesus display the magnificence of sovereign princes! And what must have been his reflections on contemplating a system of honour and emolument, set up by the professed followers of

one whose whole life was a continued scene of poverty and sufferings, and whose preaching and practice were entirely calculated to inspire all those who embraced his doctrine with a sovereign contempt for the things of this world! In the reign of Constantine the church was enriched; but it evidently appears that the spirit of genuine Christianity was in a great measure extinguished. Ecclesiastical history, which had hitherto exhibited a horrible and sanguinary scene of the sufferings of the church under pagan persecutors, then began to display a not less disgusting view of the persecution of Christians by the hand of Christians, carried on with a cruelty little short, in some instances, of that which pagans had before exercised against them.\*

To extinguish, as far as possible, the heresy of Arius, and allay other causes of schism, Constantine convoked the celebrated Council of Nice (325), which consisted of 318 bishops, and other ecclesiastics, to the number of 2048. After a session of two months, in which the emperor frequently assisted in person, the opinions of Arius, which went to a denial of the divinity of Christ, were condemned, the equality of the three Persons of the Holy and Undivided Trinity was declared the true doctrine, and being comprised in a form of belief called the Nicene Creed, was published as the obligatory and only orthodox creed of the Christian Church.†

The deliberations of the Council of Nice failed in their main design, and the Arians, persecuted by the church, dispersed themselves in distant nations, and there found a safe retreat. This may be viewed as the first great schism in the church, which henceforth consisted, not in one, but in several distinct societies of believers. To trace minutely the progress of the respective branching-off communions, would lead us considerably beyond our limits; let it suffice to say, that in the fourth and fifth centuries there were founded several important Eastern Churches. The Armenian Church dates its commencement from about the year 312. The Egyptian or Coptic Church originated in a heresy in the fourth century; and the Abyssinian Church shortly after branched off from it. The Syrian Church, in a similar manner, gave origin to the Syro-Indian Church, which still exists in Travancore and Cochin, and acknowledges as its head the Patriarch of Antioch. It is likewise to the fourth century that we must trace the origin of that great schism which afterwards divided the church into the Western or Roman Church, and the Eastern or Greek Church. At this period, the bishop of Rome occupied the first rank in the episcopal order, and on that ac-

\* Bigland's Letters on History.

† The Nicene Creed, after receiving some subsequent additions, stood as follows, and has for ages occupied a place in the church service:—'I believe in one God, the Father Almighty, Maker of heaven and earth, and of all things visible and invisible; and in one Lord Jesus Christ, the only begotten Son of God, begotten of his Father before all worlds: God of God, Light of Light, Very God of Very God, being of one substance with the Father, by whom all things were made; who for us men, and for our salvation, came down from heaven, and was incarnate by the Holy Ghost of the Virgin Mary, and was made man, and was crucified also for us under Pontius Pilate: He suffered and was buried, and the third day he rose again according to the Scriptures, and ascended into heaven, and sitteth on the right hand of the Father, and he shall come again with glory to judge both the quick and the dead; whose kingdom shall have no end: and I believe in the Holy Ghost, the Lord and Giver of Life, who proceedeth from the Father and the Son, who with the Father and the Son together is worshipped and glorified, who spake by the Prophets; and I believe one Catholic and Apostolic church; I acknowledge one baptism for the remission of sins; and I look for the resurrection of the dead, and the life of the world to come. Amen.'

With respect to the form of belief usually called the Apostles' Creed, it is believed to be of much less antiquity than the apostolic age, but there is great obscurity as to its authorship. It also has undergone alterations in the course of time. 'The third creed, erroneously ascribed to Athanasius (who assisted at the Council of Nice in 325), is affirmed to have been privately drawn up about the middle of the fourth century; and is rejected by all the Protestant churches except the Anglican.'—*Jortin's Conder's View of all Religions.*

count exerted a certain authority over all other bishops within the pale of the orthodox church. Constantine, by removing the seat of empire to Byzantium (Constantinople), raised up in the bishop of this new metropolis a formidable rival to the Roman pontiff. Accordingly, in a council held at Constantinople, in the year 381, by the authority of Theodosius the Great, the bishop of that city was, during the absence of the bishop of Alexandria, and against the consent of the Roman prelate, placed in the first rank after the bishop of Rome, and consequently above those of Alexandria and Antioch.—(*Mosheim*). The rivalry and contentions of the bishops of Rome and Constantinople which ensued from this period, terminated in 1054 in a complete rupture. Each power excommunicated the other, and henceforth the Greek Church was entirely under the authority of the Patriarch of Constantinople. The other branch of the church remained under the dominion of the Roman pontiff, and is that which is known by the name of the Roman Catholic Church.

Centuries before this latter event, the church, under the generally recognised supremacy of the bishop of Rome, had undergone the most extraordinary changes of condition. The legal establishment of Christianity as the religion of the state, and its consequent alliance with civil power, gave it a new character. That this authoritative recognition greatly aided in converting the pagan world, there can be no manner of doubt; but unfortunately, as we have seen, the wealth and authority conferred on churchmen naturally introduced evils gross in their nature; and in many respects the alliance with the civil government did infinitely more harm than good. Some writers aver that Christianity could scarcely have survived the dismemberment of the Roman Empire and the barbarism that ensued throughout the middle ages, unless fortified by civil power; but this, we humbly submit, is but a timid view of the Christian dispensation, which surely required no such extraneous means of support. It is a lamentable truth, confirmed by every respectable historian, that the proceedings of Constantine (321), and afterwards of Theodosius (390), in establishing Christianity as the religion of the empire, laid the foundation of every species of ecclesiastical abuse, and directly caused the decay of that sublime but simple piety which was the ornament of the apostolic times. It is to the arrangements consequent on the alliance of the church with the civil power, that we have also to trace the origin of that new feature in ecclesiastical polity—the endowment of churches, cathedrals, abbeys, monasteries, and other institutions, with the functionaries belonging to them. But the most extraordinary change, both in the internal and external character of the church, was the excess of power which, by the sanction of temporal princes, was accorded to the bishops of Rome. From early times, the occupant of the Roman primacy had been known under the title of *papas*, a Greek word signifying father, and hence the well-known terms *papal* and *pope*. The pope, aided by his council, formed the head of the hierarchy, and acted as a supreme magistrate in all religious matters whatsoever. From the possession of the spiritual supremacy, a plea was easily found to assume the right of interfering in temporal concerns; and, as is known to the readers of history, the pope was allowed to exercise an almost unquestioned authority over the affairs of Christian princes for several centuries. It is at the same time proper to remark that the lay and clerical members of the church did not always agree in conceding this excessive power to the popes; the right of spiritual jurisdiction was not denied; but how far, and in what manner, that of a temporal nature, without the express sanction of general councils, should be allowed, formed a point of frequent debate, and we do not know that Catholics have yet arrived at a uniformity of opinion on the subject.

Another serious abuse which crept into the ecclesiastical affairs of the church, was the establishment of monastic institutions—houses in which men secluded themselves from the world, and engaged themselves in

religious offices. The practice of living as hermits, for the purpose of religious meditation, existed before Christianity, and was only grafted upon it (in a regular manner) about the beginning of the fourth century; and in the course of the following hundred years, monasteries greatly increased in number. In the sixth century, the practice of taking vows of celibacy and rigid adherence to certain rules, was introduced by St Benedict; from which period till the tenth century, monasteries are generally allowed to have been dwellings of piety, temperance, and the refuge of learning, driven to them for shelter from the troubles of the times. In the course of the tenth and eleventh centuries, the monasteries lost this valuable character. Idleness and luxury entered their walls, together with the vices of the world; their superiors, named abbots or priors, appointed by lay princes from among the nobility, set themselves above the jurisdiction of the bishops; and in short, the whole monastic system, including convents for female devotees (nuns), became altogether corrupt. None of the religious orders rose to such eminence and power as the Society of Jesus, or Jesuits, founded by Ignatius Loyola (1491–1556), a Spaniard, and a man of great shrewdness and enthusiasm. The society was sanctioned by a bull (or ordinance) of Paul III. in 1560. Young men of ability and peculiar energy of character were alone admitted, and the trials of the novices were most severe. In addition to the usual vows of poverty, chastity, and implicit obedience to superiors, the members were bound to go, unhesitatingly, and without recompense, whithersoever the pope should send them, as missionaries for the conversion of pagans and heretics, or for the service of the church in any other way. This well-trained and formidable corps of spiritual combatants long exerted a powerful influence throughout Christendom, as well as in heathen countries; but as general intelligence advanced, they failed in their efforts; in 1773 their order was abolished by Clement XIV.; and latterly (though restored in 1814) they sunk into comparative obscurity.

The many flagrant corruptions of the church began to excite the attention of reflecting men in the fourteenth century, and efforts were on divers occasions made by them to produce a reform, but without success. The abuses chiefly complained of were the scandalous lives of many of the clergy, particularly of the monastic and mendicant orders, the gross superstitious reverence generally paid to relics, the extravagant power of the pope, and the sale of indulgences. The exhibition of religious relics, with the view of exciting the piety of believers, had degenerated into a system of pure imposture. ‘The poor fragments of mortality—a skull, a bone, or the fragment of a bone, a tooth, or a tongue—were either mounted or set, according to the size, in gold and silver, deposited in costliest shrines of the finest workmanship, and enriched with the most precious gems. Churches soon began to vie with each other in the number and variety of these imaginary treasures, which were sources of real wealth to their possessors. The instruments of our Lord’s crucifixion were shown (the spear and the cross having, so it was pretended, been miraculously discovered), the clothes wherein he was wrapt in infancy, the manger in which he was laid, the vessels in which he converted water into wine at the marriage feast, the bread which he broke at the Last Supper, his vesture for which the soldiers cast lots. Such was the impudence of Romish fraud, that portions were produced of the burning bush, of the manna which fell in the wilderness, of Moses’s rod and Samson’s honeycomb, of Tobit’s fish, of the blessed Virgin’s milk, and of our Saviour’s blood!’—(*Southey*).

The ludicrous extent to which the exhibition of relics was carried, and also the abstract claims of spiritual supremacy by the pope, might have been tolerated for some time longer; but the plenary power of selling immunities for transgressions roused the common sense of mankind. Leo X., famous for his love of splendour, commenced this odious traffic. Martin Luther (1483–1546), a monk of the order of Augustine in Germany, was

shocked with the effects of the system, as they appeared in his congregation at Wittenberg. 'By far the most notable vender of indulgences,' says D'Aubigné, 'was Tetzel, a Dominican, whose morals were on a par with his impudence. This man had popular talents: he was a ready, sonorous preacher; he was intimately acquainted with the human heart; and these advantages, joined to his dignity as prior of his order, pointed him out as the fittest person to sell these indulgences. He was accordingly made chief commissioner, and his success at the different towns he visited was prodigious. From the pulpit he declared indulgences to be the most sublime of God's favours; they had saved more souls than the efforts of all the apostles; they would atone for every sin, however heinous; they were effectual in regard to future, no less than past transgressions; they atoned for the dead no less than the living; and whoever suffered his relatives to remain in purgatory, when a little money would release them, was guilty of the worst crime. Hence a blow was struck at all repentance: contrition of heart was out of the question, when pardon could be obtained on terms so much easier. The present recital would perhaps be disbelieved, if its truth were not virtually admitted by contemporary Roman Catholics. But good is often educes from evil; and this preaching of indulgences was one of the chief causes of the Reformation. There is reason to believe that the whole system struck Luther with horror from the very first; and that, coupled with the impiety which he had witnessed in the capital of Christendom, it provoked his doubts as to the infallibility of the papal authority. The effects of the indulgences were every day before his eyes; and as one of the authorised confessors of the people of Wittenberg, he perceived them more clearly than other men. While seated in the tribunal of penance, he was amazed to hear what crimes had been committed, and still more, that no contrition was felt for them. He refused to absolve, unless the criminals forsook their evil ways. They showed him their letters of impunity: no matter; he estimated these at their just value—namely, as so many pieces of waste paper. Being dismissed without absolution, and without admission to the sacraments, the deluded purchasers complained to Tetzel, who bellowed and threatened; but Luther was undaunted: he openly preached against the pernicious traffic; he attacked the very foundation on which it rested; he denied the power of pope or church to remit the guilt of sin; and by his famous propositions, as everybody knows, rapidly produced the most gigantic change effected in this world since the origin of Christianity.'

The preaching of Luther, in exposing the error of indulgences, and calling in question various traditional tenets and practices, speedily roused a large part of Germany; and as no symptom of relenting was shown on the part of those in power, an extensive secession from the Romish Church became unavoidable. The year 1521 is to be regarded as the epoch of the Reformation in Germany; and from this period it became a political as well as religious movement—in a word, a movement in favour of civil and religious freedom. In consequence of a general *protest* being signed by the reforming party against a decree of the Diet of Spire in 1529, they received in 1541 the name of *Protestants*. Eleven years earlier, in 1530, a declaration of the principles of the reformers, drawn up by Melancthon, was presented to the emperor of Germany at a diet held at Augsburg, and there solemnly read before the assembly: this famous declaration is known in history as the Confession of Augsburg. The Reformation spread from country to country with singular rapidity: the ancient church was deposed, and one of a reformed character established in its place—in Switzerland and Geneva in 1535; in Sweden and Denmark in 1536; in England in 1547; and in Scotland in 1560. In Austria, Italy, Spain, Portugal, and France, the efforts of the reformers were less successful, and in these countries the Roman Catholic Church has been established, or at least popular, till the present day.

CONCLUDING SUMMARY.

Christianity now exists, in one or other of its various forms, in all civilised countries, and numbers, as is believed, 261,000,000, out of 900,000,000, the entire population of the globe. Although originating in Asia, and flourishing for some time in the adjacent regions of northern Africa (Church of Alexandria, for example), it prevails only to a small extent in these continents, and is principally confined to Europe and the countries which have been peopled by European emigrants. Everywhere it is the religion of *civilised man*, no other creed or form of belief being at all suitable to an advanced intelligence, or so directly calculated to inspire sentiments of refined piety, humanity, and justice. In the hands of uneducated, ambitious, and intolerant men, its history abounds in the most odious crimes; but latterly, as its professors have fallen under the influence of a civilisation to which it has itself largely contributed, and as the true principles of the Gospel have been better understood, our religion has not been outraged by indecent excesses either at home or abroad; while, by the earnest but unostentatious efforts of its supporters, of various denominations, it has been made favourably known in the most remote parts of the earth.

The forms in which Christianity is professed are very numerous, but the whole are comprehended in three leading systems—the Roman Catholic Church, the Eastern Churches, and the Protestant or Reformed Churches.\* With but one exception, all acknowledge

\* *Roman Catholic Church*.—The doctrines and ritual of this body, as now professed, proximately rest in a great measure on the decisions of the Council of Trent (terminated 1563). According to these decisions, the Romish creed embraces the following points:—An admission of apostolical and ecclesiastical traditions; that the Holy Scriptures form only a part of revelation, and are to be interpreted only according to the sense in which they are held by the church; that there are seven sacraments necessary for the salvation of mankind, though not for every one—baptism, confirmation, eucharist, penance, extreme unction, clerical orders, and matrimony; that in the mass there is offered a true, proper, and propitiatory sacrifice for the living and the dead; and that in the holy sacrament of the eucharist, there is really, truly, and substantially, the body and the blood, together with the soul and divinity, of Christ (transubstantiation); that there is a place of purgation, or purgatory, into which souls proceed after death; that the saints, reigning together with Christ, are to be honoured and invoked; that they offer prayers to God for us, and that their relics are to be had in veneration; that the images of Christ, of the Virgin Mary, and also of the other saints, ought to be had and retained, and that due honour and veneration are to be given to them; that the power of indulgences was left by Christ to the church, and that the use of them is most wholesome to the Christian people; that the Holy Catholic Apostolic Church is the mother of all churches, and that out of the Catholic faith none can be saved. To these principal matters of belief are added—the efficacy of prayers for the dead; auricular confession; celibacy of the clergy; the use of Latin in the public ministrations; signing with the cross; the rosary as an implement of devotion, &c.

The Roman Catholic Church is an episcopacy, or government by a hierarchy of bishops. The supreme control rests in the pope and his council at Rome, and thence radiates a system of management, most complete and effective, over all parts of Christendom. The church includes three distinct orders of clergy—bishops, priests, and deacons; all others—such as cardinals (pope's expectant), archbishops, deans, vicars, &c.—belonging to one or other of these classes. The church claims the mark of true *apostolicity*—that is, an unbroken line of descent from the apostles and their Divine Master. The ordination of priests is the engrafting of them into this apostolic line of succession. Bishops alone ordain or communicate holy orders. In no church is the ritual of public worship so highly adorned, or rendered more imposing, by the dresses of the officiating priests, the waving of censers, crucifixes, pictures, images, and music. Although celebrated in an unknown tongue, it is observable that the public worship excites the greatest appearance of attention and decorum, as well as all the outward demonstrations of piety. The influencing of the devotional feelings is said to be the object aimed at by the various outward insignia; the church (if we understand the argument) holding it to be of equal consequence whether the heart is touched, and feelings of piety and veneration

the doctrine of the Trinity, the fall of man, salvation by the expiatory death of Christ, the resurrection, and a state of final rewards and punishments. Differences on other matters may be traced to two distinct causes of controversy.—1. Whether the rule of faith and practice is absolutely confined to the Holy Scriptures, or embraces a traditional revelation, sanctioned by councils, and cherished by the church? 2. And who has the right to interpret the rule of faith

tion are excited, by the exhibition of a crucifix, or the preaching of a sermon. The Roman Catholic Church, though now only a remnant of its former self, is still the most numerous of the various Christian bodies: it includes within its pale France, Belgium, Poland, Italy, the Mediterranean islands, Spain, Portugal, the greater part of the people of Austria and Ireland; about a half of the Prussians and Swis, and the inhabitants of various German states; large numbers in the South American states and Mexico; also a part of the population of the United States, and nearly all the Lower Canadians; and a considerable number of the inhabitants of England and Scotland, besides those of inferior countries. Altogether, the number of Roman Catholics is said to amount to 138,000,000.

The *Eastern Church* is divided into four leading communions, and several of a subordinate rank.—1. The Constantinopolitan or Orthodox Greek Church, comprising all who acknowledge the supremacy of the Patriarch of Constantinople. 2. The Russian Greek Church, which prevails over Russia, and in virtue of an ordinance of Peter the Great, in 1700, was constituted the national church, having for its head the Russian emperor; it is governed by a council at St. Petersburg. 3. The Anti-Byzantine or Monophysite Churches, which have renounced communion both with the Constantinopolitan Church and Church of Rome, and differ from both in doctrine and ritual: these churches include the Syrian, Coptic, Abyssinian, Nestorian, Indo-Syrian, and Armenian Christians. 4. The Greek and other Eastern churches, including the Maronites in Syria, who are in communion with the Church of Rome. The whole of these Eastern churches are said to include 69,000,000 of members. Whatever be their peculiar differences, all recognise two sources of doctrine, the Holy Scriptures and Tradition, and are hierarchical episcopates in their form of government. The church service is in Greek. 'The rites and ceremonies of the Greek Church are exceedingly numerous, trivial, and burdensome. In all the services except the communion, prayers and adorations are offered to the Virgin (styled the *Panagia*, all-holy), or to some of the multitudinous saints of the Greek calendar, almost as often as to the Deity. Every day in the year is consecrated to some saint, frequently to more than one; and every day of the week is appropriated in the church service to some peculiar object of adoration.—*Conder*. This church does not resist the circulation of the Scriptures, and its clergy may be married men.

The *Protestant Churches* are either those which split off from the Church of Rome at the Reformation, or others which have since sprung from the reformed bodies. Protestantism owns two fundamental principles—that the Bible contains the sole rule of faith, and that it is the right of every one, without respect of person, to judge of that rule with all the aids which Divine grace, reason, and conscience, can inspire. At the same time, it may be noticed that generally in practice each church possesses certain standards of belief to which it is expected its members will adhere. Rejecting traditional revelation, and the decrees of all councils but those of an early date, Protestants admit only two sacraments—baptism and the Lord's Supper. They reject transubstantiation and the sacrifice of the mass; deny the lawfulness of monastic vows, the holiness of celibacy, the merit of good works, the virtue of indulgences, the invocation of saints; reject the worship of images, auricular confession, extreme unction, purgatory, prayers for the dead, and the spiritual authority of the pope. Protestantism exists in three main divisions—Lutherans, Armenians, and Calvinists—each differing from the others in certain points of faith and church government; but there are, besides, innumerable sects which cannot be included in these bodies—as, for example, Quakers, or the Society of Friends, who reject the lawfulness of clerical functionaries, and disapprove of the sacraments and all ordinary forms of public worship—Baptists, a numerous body, with recognised pastors, who possess a very simple form of church government, repudiate infant baptism, and maintain the necessity of the baptism or immersion of adult believers—Moravians, a large and unobtrusive body, who, among other good qualities, display extraordinary ardour in the prosecution of missionary labours—Methodists, a numerous body in England, chiefly distinguished for their devotional fervour, the reformation of manners, and the instruction of the young in

—the church or individuals! On the exact determination of these points rests a complex series of divisions, which at present appear to be as far from settlement to the mutual satisfaction of parties, as they were in the sixteenth century; and we may rationally conclude that, humanly speaking, little or no advance to reconciliation can be effected till education has dispelled the mists of prejudice, and enabled men to perceive and judge of abstract matters more equably.

religious duties by means of Sunday schools—and Unitarians, an intelligent and respectable body, but differing widely in doctrine from all other classes of Christians; who maintain, as their name imports, the absolute unity of God, in opposition to the doctrine of the Trinity, acknowledge no fixed creed or standard of faith except the Bible, and reject the doctrines of original sin, the vicarious sacrifice of Christ, and the eternity of future punishments. The total number of Protestants, of all churches and sects, is believed to be about 61,000,000.

Protestantism is professed in two chief forms—*Episcopacy*, or the government of the church by bishops, whose spiritual authority is derived from the apostles through the efficacy of ordination, both before and since the Reformation; and *Presbytery*, which rejects a hierarchy of bishops, and admits only the government of the church by a body of ministers all equal in rank. The body called *Independents*, or *Congregationalists*, only admit of each church being governed by its own members, on a primitive and simple model. At the head of the Protestant Episcopal churches may be placed the Church of England, whose doctrines are contained in the well-known Thirty-Nine Articles and in the Book of Common Prayer. The Church of England has for its basis a denial of the supremacy of the bishop of Rome, and rejects the doctrine of purgatory, the doctrines concerning indulgences and pardons, the worship or veneration of images and relics, the invocation of saints, the sacraments of confirmation, penance, orders, matrimony, and extreme unction, transubstantiation, and the sacrifice of the mass. It retains confirmation as a religious ceremonial, ordination to the priestly office, the sign of the cross in baptism, burial service, kneeling at the communion, absolution of the sick, the whole hierarchical routine of officials—bishops, priests, deacons, prebends, archdeacons, rectors, vicars, &c., and numerous fasts and festivals. In its calendar (see No. 78), affixed to the Book of Common Prayer, there are retained the names of about seventy saints of the middle ages, such as Hilary, Priscilla, Valentine, Dunstan, &c. Practically, the church pays no attention to these, or to most of the authorised fasts, festivals, vigils, &c. According to law, the reigning sovereign, whether a king or queen, is head of the church, and has the appointment of its bishops, who hold the dignity of spiritual peers, and are members of the legislature. From its strict connection with the state, the Church of England labours under the misfortune of possessing no power in itself to amend its formularies, which consequently remain what they were in the reign of Edward VI.; yet this great disadvantage is felt to be comparatively unimportant, on account of the extraordinary beauty and simplicity of the language of the prayers and litanies, as well as the elementary nature of the whole service, which admits of no alteration by officiating ministers. [The Book of Common Prayer was prepared by order of Edward VI., who issued a commission, consisting of thirteen English divines, with Archbishop Cramer at their head. The commission met at Windsor, May 1548, and drew up a Book of Common Prayer, which was approved by convocation, and finally ratified by an act of parliament in the January following. This book, which is substantially the same as our present Common Prayer Book, was enjoined to be used for all divine offices, from the Feast of Whitsunday 1549.] Both in the United States of America and in Scotland, there are Episcopal communions deriving ordination from the Church of England, and having the same form of worship.

*Presbyterianism* is established in Scotland, Holland, and some of the Swiss cantons, and exists to a large extent in North America. Presbyterians generally follow the doctrines of John Calvin, rejecting the use of crucifixes, the sign of the cross, altars, liturgies, &c. and recognising no saints' days. Christmas and Easter are recognised by Presbyterians in Holland, but not by those in Scotland. The clergy, being equal in rank, are governed by provincial and general courts, constituted from their own body. Scotland possesses a numerous body of Presbyterian dissenters or seceders from the establishment; and latterly these have added to former causes of difference, by declaring their hostility to all connection between Church and State; and that Christianity, as was the case prior to the era of Constantine, should be entirely independent of civil government, and its ministers supported exclusively by voluntary contributions.

## PAGAN AND MOHAMMEDAN RELIGIONS.

RELIGION is a general habit of reverence towards Deity, whereby we are inclined to worship and serve Him, so as to procure His favour and blessing. In this sense, the term applies to all forms of belief—to an ignorant trust in imaginary deities, as well as to a knowledge of the true Creator and Preserver. The word religion is from the Latin, and means literally to *bind again*; that is, to present a new and sufficient reason for virtue, and the hope of a state of blessedness after death.

### PAGANISM.

Paganism is a term of wide import, and includes a belief in heathen deities, as well as the practice of the wildest superstitions. The whole of the ancient world, excepting the Jews, were pagans, and under various symbols worshipped imaginary deities. (See HISTORY OF ANCIENT NATIONS, and also the succeeding sheet on SUPERSTITIONS in general.) We shall notice here some of the principal forms of paganism:—

### FETISHISM.

Fetish is a word which is believed to be derived from the Portuguese language, and signifies any object in nature or art to which a superstitious reverence is attached. Fetichism is the lowest existing form of paganism. It is universal, one kind or other, throughout various countries in Asia, Africa, and also islands in the Pacific and Southern Oceans. It is the religion of ignorant man, groping for deity, seeking for something which he can venerate and fear. In Southern Africa every tribe has its own variety of fetishes. In Whiddah, a small insect called the creeping leaf is highly honoured. Some species of serpents also are worshipped in temples by priests set apart for the purpose. In Benin, fetishes are more numerous, and, in part, of an entirely different description. The whole material universe is believed to be animated and furnished with spiritual powers: water, land, animals, stones, trees, and vegetables of every description, are all full of divine spirits and secret influences. He who makes any stable article his fetish, touches nothing of that sort whatever, whilst he consumes, without the slightest hesitation, what others consider holy. There is a depth and mystery in this superstition which cannot be very clearly understood. As far as can be reasonably conjectured, this species of fetichism implies a connection between the visible and invisible, and that everything may by certain means be made to have a relation to man and his destiny. The quality of the thing arbitrarily set apart and invested with an attribute of divinity is of no consequence: it may be a piece of bone, rag, egg-shell, or clay, indeed no matter what; there must merely be a belief of a relation subsisting between it and man, which relation often commences only for the first time when the thing is consecrated; in a word, everything properly consecrated and revered as the residence or tangible investiture of deity, is supposed to have a divine power, which, when evoked, is able to incline the Deity to comply with the wishes of men. Under different names, this superstitious reverence for visible objects has prevailed in nearly all ages and countries. The Lacedæmonians had a sacred stone, which, at the sound of a trumpet, is said to have raised itself to the surface of the water from the bottom of the Eurotas. The ancient Germans and Gauls had also their holy rocks, caves, seas, springs, and trees, which afforded miraculous aid, and delivered oracles. In Iceland there was a stone in which a divine spirit was supposed to reside, and was therefore an object of religious worship. The Laplanders had a sacred mountain and a consulting drum. All these

superstitions are as absurd and irrational as the fetichism of the Negroes; they are, indeed, prompted by the same hopes, fears, and feelings.

According to the visionary ideas of some ancient sages, a divinity was supposed to reside in matter, and to be liable to be roused from its latent state into activity by means of consecration and the performance of solemn mysteries. In some of the islands of the Pacific, if any person wishes to protect his property, such as a house, field, or place of sepulture, from robbery or intrusion, he declares that it is *tabooed*, or placed under the guardianship of his gods; and the belief that such is the case being universal, the property is safe from aggression. Mr Ellis, in his 'Missionary Tour through Hawaii,' mentions some interesting particulars regarding the superstitious delusions of the natives, which incline us to think that these remotely-situated people must have had some early connection with the ancient natives of Asia and Africa, from whom the Greeks and Romans imported their learning and mythological observations. These Hawaians, as we are told, previous to their embracing Christianity, believed in a number of ideal gods, who were ministered to by priests, and were propitiated by sacrifices of animals: in making these sacrifices, the diviners observed 'the manner in which the victims expired, the appearance of the entrails, and other signs. Sometimes, when the animal was slain, they embowelled it, took out the spleen, and holding it in their hands, offered their prayers. If they did not receive any answer, war was deferred. They also slept in the temple where the gods were kept; and after the war-god had revealed his will by a vision or dream, or some other supernatural means, they communicated it to the king and warriors, and war was either determined or relinquished accordingly.' The images of the gods who constituted the guardians of the tabooed places of sepulture are described as figures oddly carved in pieces of wood; these were stuck on the fences and trees of the enclosure, and with their horrid aspect and ragged garments, seemed no improper emblems of the system they were designed to support. Adjoining the sacred enclosure the author was shown a *Pahu Tabu*, or City of Refuge, which was open for the reception and security of all classes of delinquents, and resembling in its regulations the sanctuaries of antiquity. These, and some other circumstances mentioned by Mr Ellis, open an interesting field for speculation on the probable connection of ancient and modern superstitions, or at least on the similarity of the delusions by which the untutored human being has in all ages been affected.

It is gratifying to think that these absurd superstitions have in many of the Pacific islands, by the philanthropic exertions of Christian missionaries, been entirely rooted out; and that from other quarters of the globe the most cheering intelligence continues to be received that the reign of idolatry is on the decline, and that there are good hopes of its speedily being overthrown by the diffusion of the mild and elevating doctrines of a purer faith. From various parts of Africa we learn that Christianity is making encouraging progress, and has already been instrumental in emancipating many of the natives from the influence of fetichism and other degrading superstitions. In the interior of that continent, as we learn from recent travellers, fetichism exists to a lamentable extent; and so long as Africa continues to furnish the Christian world with slaves, we may rest assured that this system remains in vigorous exercise.

Fetichism has long been practised among the Negroes of the West Indies under the name of *Obeah* or *Obi*—a term most likely originating in Egypt and the adjacent

parts of Africa, where anciently there was a deity of a demoniacal character, with the name Ob or Oub, and from which Moses commanded the Israelites to abstain from making inquiries. Obi is therefore one of the exploded oracles of the ancient world, which has been carried by captured Negroes to the West Indies, and there set up as an oracle and the patron of incantations, charms, and all other superstitious delusions. The adepts who practise this kind of fetishism are called Obeah-men, or Obeah-women, for both sexes engage in the mysteries of this species of jugglery and imposture. We believe that since the abolition of slavery in the West Indies, and the spread of education and Christianity, the practice of Obi has gone out of repute and notice.

At one period the religion of the Parsees or Fire-worshippers existed throughout Persia and other parts of Asia, but is now confined chiefly to the deserts of Caramania, towards the Persian Gulf, where it is followed by the Guebres or Giaours (infidels), as they are called by the Mohammedans. The great prophet or improver of the Parsee religion was Zoroaster, who flourished about two thousand years ago, and taught the doctrines of there being an eternal spirit of Good or Light (Ormuzd), and an eternal spirit of Evil or Darkness (Ahriman), with a vast number of inferior good and bad genii. In this there was a glimmering of a pure theism; but besides a variety of absurd imaginations respecting the organization of nature, the belief in one God was obscured by a typical worship of the sun, and of fire, both being supposed emanations, or at least emblems, of the spirit of Good and Light. Fire-worship, as practised by the Persian magi, disappeared before the spread of Christianity and Mohammedanism, and, as we have said, exists chiefly among the Guebres, a detached remnant of the old Persian nation.

#### HINDOOISM.

Hindooism or Brahminism is the religion professed by a majority of the inhabitants of Hindoostan; and while possessing the force of great antiquity, it is supported by a skilful priesthood and the division into castes, rendering it the most ineradicable of any system of false belief which exists (See EAST INDIES, No. 67).

The Hindoos recognize the existence of a supreme and invisible Ruler of the universe, entitled Brahma, but at the same time believe in the existence of other two deities, one of whom is Vishnu the Preserver, and the other Siva the Destroyer. Previous to the creation, Brahma is said to have reposed in silence and self-absorption—a mode of existence considered by the Hindoos as the most perfect and godlike. Having a desire to draw out of his own divine essence a glorious creation, to supplant the deep primordial gloom, he by a thought created the water, and deposited therein a golden egg, blazing like ten thousand suns, which remained inactive for millions of years, till Brahma, who lay enclosed in this shining receptacle, by the energy of his own thought, split it asunder, and sprang forth the Divine Self-Existing, famed in all worlds as the creator of rational beings and the forefather of all spirits. Brahma is represented as a golden-coloured figure, with four heads and four arms; but although he gives name to the great caste of the Brahmins or priests, no sects derive their distinctive appellation from him. He attracts little attention or worship, and he has neither temples erected, nor sacrifices offered to him, nor festivals celebrated in his honour.

Vishnu makes a very conspicuous figure in the sacred annals of India, and the fundamental idea of the Hindoo religion, that of metamorphoses or transformations, is exemplified in the *avatars*, or appearances upon earth of this deity. In his character of preserver, or rather deliverer, he has, say the Vedas, interposed whenever any great calamity threatened the world: and thus the great ends of his providence are brought about by the various incarnations of the Hindoo deity. Of these transformations there are ten, and they fill up the Indian *yugs*, which compose a certain series of periods intended to effect a junction with God, and comprising

4,320,000 years. The *yugs* have been considered as an allegorical description of the year, divided by the solstices and equinoxes, and of the procession of the equinoxes. Nine *avatars* have already taken place, and the tenth is yet to come.

It is unnecessary to dwell at any length on the wonderful and ridiculous *avatars* of Vishnu. He first appeared in the character of a fish, for the purpose of recovering the sacred writings given by Brahma, which had been swallowed by a giant (typical of the rebellious human soul), and buried along with himself in the depths of the ocean. He successively appeared as a tortoise, a boar, a man-lion, what is called the Brahmen or lingam dwarf, and so on. The transformations are of the most ridiculous nature; and were we to recite them, they should only excite pity for the ignorance of the wretched believers in such absurdities.

In his subsequent *avatars*, under different forms, Vishnu delivered the world from successive monsters and giants which threatened its tranquillity. In the ninth *avatar*, which is supposed to have taken place in the year 1014 before the Christian era, Vishnu assumed the form of Boodh, the author of a rival creed distinct from that of Brahma. It appears pretty evident that Boodhism at one time very extensively prevailed throughout India; and several great dynasties, particularly that of Magadha, were Boodhist. But a war having taken place between the devotees of Brahma and those of Boodh, the latter were worsted, and dispersed throughout the countries to the east and north of Hindoostan, and Boodhism is no longer professed in India. The rival systems will be noticed after we have described the other deities, male and female. In the tenth *avatar*, Vishnu will descend to the earth mounted on a white horse, and armed with a scimitar blazing like a comet, to root out evil from the earth, and eternally to punish the wicked. Vishnu is represented of a black or blue colour, with four arms, and a club to exercise chastisement on the wicked. The emblems under which he is represented refer to his vindictive character. He has three eyes, to denote the three great divisions of time—past, present, and future. A crescent in his forehead refers to the measuring of time by the lunar revolutions, as a serpent denotes it by years; and the necklace of skulls which he wears, the extinction of mankind in successive generations.

The third member of the Hindoo triad is Siva the Destroyer. It may be here remarked that the distinguishing appellations applied to these deities are not altogether characteristic of their functions—Vishnu the Preserver frequently employing himself in acts of destruction, and Siva, on the other hand, in acts of beneficence. But much vagueness, inaccuracy, and confusion prevail throughout the whole of the Hindoo creed; and this no doubt arises from the love of the marvellous and indescribable, by which they are led to grasp at phantoms of thought as undefinable as they are impalpable. Siva, it appears, has had an equal share of personal adventure with Vishnu, although the characters which he assumed were not so various, nor his exploits so important or striking. His female partner is called Doorga, and to her the appellation of destroyer is more applicable than to him. She is the chief amongst the female deities; in short, the most formidable and warlike personage of the Hindoo pantheon. She has rivalled Vishnu in the number of forms which she has assumed, and the conflicts in which she has borne the most conspicuous part; and the giants and others who have fallen victims to the prowess of her arm, occupy a prominent place in the wild records of Hindoo mythology. As an object of adoration, the appearance which she is made to assume shows a remarkable obliquity of moral vision in those who framed at first, and those who worship still, this horrible personage. Under the name of Kalee, she is black, with four arms, wearing two dead bodies as earrings, a necklace of skulls, and the hands of several slaughtered giants circling her waist like a zone. Her eyebrows stream with blood; and not content, as the

male divinities generally are, with the simple productions of nature, her altars are made to flow with the blood of animal oblations. Old records even give directions how human sacrifices are to be offered to this cruel goddess. India has no deity more popular, not only amongst banditti, who hold her in especial veneration, but with the more reputable classes of the community, who offer lavish gifts on her shrine. The disgrace of her religion consists in the worship of impure imagery, which it is impossible to mention.

It is unnecessary to enumerate even the more important of the minor deities; as for the whole, they are altogether innumerable. Some have taken the trouble to reckon up three hundred and thirty millions of them. There are gods of the elements, of war, of the sun, of the winds, of fire, of water, and so on. Every river, fountain, and stream, is either a deity itself, or has one presiding over it. The worship or deification of the Ganges forms a distinguishing element in the belief of the Hindoos. Into this large river all who dwell within a certain distance of its banks crowd morning and evening to bathe; and the water of this sacred stream is carried to all parts of India, and is sworn by in courts of justice. At Allahabad, where the streams of the Ganges and Jumna unite, the country for many miles round is considered sacred ground; and so great is the number of pilgrims who resort thither for bathing, that the vizier has received in one year half a lack of rupees for permission to enjoy the benefit of immersion in the sacred flood. Oftentimes may be witnessed children hurrying their parents to the river side, fearful lest they should die before being able to reach its banks. Nothing can be more distressing to the feelings than to behold these poor expiring creatures, some calling upon Rham, some upon one of their false gods, others upon another, with their bodies half in the water and half out, the rising tide soon to overwhelm them. Many are stretched out where the tide cannot reach them, and their case is more pitiable still. Beneath a burning sun, they are left without food, and great numbers, who would no doubt recover from their diseases if proper attention were paid to them, are literally starved to death, or devoured by jackals at night.

Amongst the degrading doctrines of the Hindoo faith, a veneration for, and even a worship of, members of the brute creation is not the least remarkable. The cow, in particular, commands the most exalted reverence; and this venerable quadruped may be seen in cities sauntering up and down in the most public places, perfectly at her ease, and calling forth expressions of profound respect. The monkey likewise ranks amongst the higher grade of animals, and is allowed to roam at large wherever he lists—a chartered thief, now laying the confectioner's sweetmeats under tribute, and anon taxing the fruiterer for a portion of his juicy store. But this superstition reaches its climax in the hospitals which are erected for affording shelter and succour to sick and infirm brutes, including lice, fleas, and other insects. It must be an exceedingly nice investigation for those who preside as medical attendants over such institutions, to determine the state of health of such patients. Other animals besides these are held sacred, but some quadrupeds are treated with great cruelty. The draught horses, in particular, Bishop Heber informs us, are barbarously abused; nor is there much sympathy shown to human beings, who are often allowed to perish from disease or hunger under the canopy of heaven, without awakening a sigh in the bosoms of the onlookers. Lepers are regarded as objects of divine wrath, and are treated accordingly, sometimes being burned or buried alive.

The peculiar character of the Hindoo creed is derived from their tenet respecting the transmigration of souls. The spirits of the dead are said to enter a receptacle corresponding to the previous character of the individual. The immortal part of the just and good, however insignificant the person may have been, migrates into a hermit, a Brahmin, a demigod, and so forth,

rising in dignity according to the degree of merit. The wicked, on the other hand, not only are degraded as human beings, but are compelled to lodge in the bodies of animals. The Hindoo oracles endeavour to establish a degree of conformity between the punishment awarded and offences committed. The pilferer of grain is metamorphosed into a rat, and he who stole fruits or roots becomes an ape. Others are degraded into worms, insects, and so on. The person thus lowered in the scale of creation must pass through a long succession of degraded births before he can reassume the human form. This system of rewards and punishments, although confined to the earth, does not exclude the belief of a heaven and a hell hereafter. The celestial mansions, like those of the Mohammedan, are replete with objects of voluptuous enjoyment; but only Brahmans and persons of high attainments or great sanctity are permitted to enter these blissful abodes. Some ardent devotees aspire to a higher destiny, and hope to be absorbed into the essence of the Supreme Being, where they shall repose for ever on an unruffled sea of bliss. The place of final punishment, in like manner, consists of different compartments, the penalties inflicted in which correspond to the iniquities of those who are doomed to enter within their dismal precincts.

The devotion of the Hindoos consists in a system of ceremonious observances, not only troublesome in themselves, but encroaching on the moral duties, nay, the whole business of life. Such a stock of atoning merit is by this means conferred, that the weightier matters of the law seem to be superseded; at all events this external devotion is not inconsistent with the most scandalous crimes. The observances commence in the morning with ablutions and prayers, the worship of the rising sun, in the inaudible recitation of their holy writings, in meditation, and the like. The five sacraments are then performed, which are, teaching and studying the sacred books, offering cakes and water, an oblation of fire, in giving rice and other food to living creatures, and in receiving guests with honour. The whole of these ceremonies are necessarily abridged, for the entire day would scarce suffice for their perfect performance. The early Hindoos seem to have borrowed, and to have greatly extended, the typical impurities of the Mosaic law; and the rules on this subject, pointing out the causes of defilement and the modes of purification, are numerous and absurd. The death or birth of a child, touching a dead body, a newborn child, a Pariah or outcast, and so on, render people unclean; and the modes of purification are either bathing, stroking a cow, looking at the sun, or having the mouth sprinkled with water.

Penance and self-torture are regarded as essential to the attainment of a character for holiness; but in their attempts to suit the amount of penance to the magnitude of the offence, there is almost a total subversion of all moral distinctions. Acts naturally indifferent are classed with heinous immoralities; for instance, eating things forbidden is put on the same footing with killing a friend, and drinking forbidden liquor with killing a Brahmin. A particular class of devotees, called *yogues* or *fakirs*, signalise their piety by enduring the severest tortures with a firmness and perseverance worthy of the holiest cause. These consist in burying themselves in the depths of forests, either in a state of perfect nakedness, or having their bodies coated with ashes and cow-dung; in allowing the nails of their hands and feet to grow till they assume the dimensions and appearance of bird's claws; roasting themselves before huge fires; immuring themselves in the ground, and leaving only a small breathing-hole; going about with small spears or rings pierced through the most tender parts of the body, and hot irons applied to the side; holding their hands above their head till they have lost the power of bringing them down again, and become withered like that of the individual mentioned in the Evangelists; clenching the fists till the nails penetrate the palms; turning their faces to the sun till they cannot regain their natural position, or gazing on his in-

tense blaze till their eyesight is extinguished; lying on iron spikes; tearing the flesh with whips; chaining themselves for life to the foot of a tree; and performing other such-like acts of slow suicide. Some of their attitudes are exceedingly fantastical; for instance, Bishop Heber saw a devotee hopping about on one foot, having made a vow never to put the other to the ground, which was now shrivelled up, contracted, and useless. Begging holds a conspicuous place among the religious duties of the Hindoos. Mr Ward affirms that an eighth part of the inhabitants of Bengal and Bahar subsist in this manner; thus constituting a mendicant population of upwards of two millions. Religious pilgrimages are held in high esteem, and the holy places have generally been established near the sea, the sources and junctions of rivers, the tops of remarkable hills, hot springs, caves, waterfalls, and places of difficult or dangerous access. All the principal roads are crowded with people hastening to these holy places. Some are held in higher veneration than others; and it is no uncommon occurrence, in the crush and tumult of the multitude to reach these fabulous Bethsadas, for numbers to be trodden to death under foot, or precipitated into the water and drowned.

The sacred writings of the Hindoos are of two kinds—the Vedas and Shastrea. The former may be termed their Scriptures, the latter expositions of them. The Vedas are divided into four books, all written in the Sanscrit language. The first book is called *Rug Veda*, which signifies the Science of Divination, concerning which it principally treats. The second is distinguished by the title of *Sheeham*, which signifies Piety or Devotion; and this book treats of religious and moral duties. The third is the *Judga Veda*, which, as the word implies, includes the whole science of religious rites and ceremonies. The fourth is denominated *Obater Bah*, or the knowledge of the Good Being, and accordingly this book comprehends the whole essence of theology and metaphysical or moral philosophy. These various books are acknowledged to be of great antiquity, but abound in such absurdities, as to be of little or no value as historical documents.

The temples for the celebration of Hindoo worship appear to have been in ancient times of the most magnificent description, as is proved by the remains of those of Elephanta and Salsette. The temples of the present day do not exhibit such elaborate grandeur, many containing only one apartment, and few having more than three or four. The crowds which besiege them on solemn occasions celebrate their observances in an open area fronting the gates, so that nothing is required within but accommodation for the images, and one or two attendants. The idols are composed of every possible kind of material, from gold down to wood or clay, smeared over with a little red paint. Any figure, either of brute or man, or centaur-like combinations of both, serves for a god, and is revered as such by the ignorant Hindoos, after a Brahmin has consecrated them by a process of solemn buffoonery. When placed in the temple, every image has a daily round of homage performed before it, and is furnished with a regular allowance of food, which, after remaining for a limited time, is served out amongst the attendants. These offerings are profusely lavished on great annual festivals, whilst the multitudes without sing indecent songs, and throw themselves into the most fantastical attitudes and motions. The various articles of maintenance bestowed upon the goddess Kalee, for example, in her temple at Kaleeghata, are considered by Mr Ward as worth about £9000 annually.

There is no doubt that, at no very distant period, the bloody deities of the Hindoos were propitiated with human sacrifices; and in confirmation of this, some of the rites still remain. Children were sacrificed by being thrown into the river Ganges, until the practice was put a stop to by the British government. Old women are still occasionally burned, in order that their spirits may haunt the spot where they are offered up, and entail a curse upon it. The *suttee*, or custom of a widow

burning herself on the funeral pile of her husband, was a well-known and common rite of the Hindoo religion, till prohibited by order of the British government; and the festival of Juggernaut, another sanguinary ritual also happily on the decline, is celebrated by the sacrifice of numerous victims. This idol-car is a lofty ornamented structure, in which are representations of the god, and of Bala Rama and Soobhadra, said to be his brother and sister. This infernal machine, for it deserves no better name, is dragged along amid shouts of triumph by the infatuated multitude, its path being marked by the bodies of mangled victims, who voluntarily throw themselves before the wheels, and are crushed to death. The most indecent figures are portrayed on the chariots used at the temples. With such an impure religion, it is not a matter of surprise that the state of morals is very low in India.

From time to time during the lapse of ages, various sectaries have arisen amongst the Hindoos, each with peculiar objects of adoration and modes of worship. Brahma, as already observed, is at the head of no sect; and Vishnu and Siva, the two powers next to him, divide in a great measure the worship of Indian devotees. Among forty-three leading denominations, Mr Ward reckons twenty to attach themselves to Vishnu, nine to Siva, four to his wife Doorga, under the name of Saktas, while ten select inferior objects of adoration. The zealous adherents of the rival sects of Vishnu and Siva are avowed enemies, and hold each other up to odium and ridicule. But the most important schism is that between the disciples of Brahma and the adherents of Boodh, to which allusion has already been made. The latter have objects of worship, a creed, ceremonies, and institutions entirely peculiar. Their temples are much more splendid than those of the followers of Brahma, and their priests live in spacious convents. Boodhism is no longer professed in India Proper, but there is a sect called the Joinas, very numerous in Western Hindoostan. They combine in some measure the practice and doctrine of the two rival systems.

The Sikhs, who recently offered such formidable opposition to the British dominion in India, are the only sect in Hindoostan who have abjured the errors of Hindooism, and adopted a purer and more rational creed. Their founder, Nanuk Shah, who was born A. D. 1469, was an able and good man, and was anxious to effect a union between the Mohammedans and Hindoos, and for this purpose endeavoured to prevail upon the members of both sects to forego those parts of their respective systems which were not essential to the maintenance of a pure and holy life. He succeeded in obtaining numerous disciples; and his elevated religion, united to the immaculate purity of his life, gave him great influence, both of a temporal and spiritual nature, over those who embraced his doctrines. Even to this day his followers continue to venerate his memory; and notwithstanding the persecutions to which they have been subjected by their Mohammedan neighbours, they have continued to receive such accessions to their numbers, and have approved themselves such distinguished warriors, that it lately required no small effort on the part of the greatest military power in India to repel their aggressions. It is a remarkable circumstance that the Sikhs should have been able to receive and to maintain so pure a creed in the midst of the grossest idolatry; and the formidable opposition which they have succeeded in presenting to such powerful enemies as they have had occasion to contend with, shows the tendency which freedom from degrading superstition evidently has in elevating the human character. Had they continued to adhere to the ancient usages of their country, it would have been impossible for them to maintain their position as they have done; for the distinctions of caste, and the interminable ceremonies enjoined by the Hindoo faith, tend not only to deteriorate the mental and bodily powers, but to make serious encroachments upon the time which ought to be dedicated to the active and necessary duties of life.

Decidedly the most vicious part of the Hindoo religion

## PAGAN AND MOHAMMEDAN RELIGIONS.

is the division of the people into castes, or distinct classes, for such an arrangement strikes at the very root of social progress, and prevents all rational improvement. The whole Hindoo population is divided into four branches or tribes, denominated Brahmins, Kyetra, Bhyssa, and Soodra. The rank, occupation, and duties of these several castes are fully explained in their Vedas, or holy books. The Brahmins are the priests; they are required to be virtuous, learned, just, peaceable, and self-denying. If these were ever the distinguishing traits of their order, the very reverse are the features of their character now. The Kyetra is the military caste: the Vedas require of them a thirst for glory; to die rather than retreat; generosity and princely conduct to captives. Bhyssa form the agricultural part of the community; their duties are briefly defined as cultivators and traffickers. The fourth or Soodra caste consists of labourers, who are enjoined to serve with patience and fidelity; the former, perhaps, they generally do, but as for the latter, it is only when constrained by fear of punishment or loss of pay. The two middle castes have almost become extinct, or rather amalgamated with the former and latter. Thus it may almost be said that the whole Hindoo nation is now composed of Brahmins or Soodras, both of which are divided into a great many degrees or sub-castes, so that there are many orders of Brahmins as well as of Soodras. Of the latter, the Koit is the highest, and the Hurry the lowest, which caste embraces shoemakers, mat-makers, bird-catchers, tanners, skimmers, snake-catchers, and many others similarly employed.

By this division of caste or grade, no possible means exist for any person to rise in the scale of society; all motives to exertion or mental improvement are cut off; no actions, however noble, no discoveries, however important to society, would insure honour to a person of low caste; and those of high caste lose no honour or reputation by their ignorance and vice. Whatever be the mental abilities of a Hindoo, if born a Soodra, a Soodra he must remain; if the father be a snake-catcher, all his sons must be snake-catchers too; and the influence of caste follows him through all the ramifications of life. Persons of different castes or occupations cannot eat, drink, or smoke together; neither can they intermarry, nor meddle with each other's employment. If a Hindoo loses caste, which is the case if he breaks through any of the foregoing rules, the most distressing consequences ensue: no one will eat with him, or suffer him to come near his dwelling, or marry his children; his own wife and family disown him; looked upon as an outcast of society, he is deprived of all privileges, or means of comfort as long as he lives; and however respectable he may have been before, the meanest caste consider him a vagabond, and will not associate with him. It is caste that renders so many servants necessary to do the work which one or two might easily accomplish. They are born to one particular department of service, and no other can they perform without losing caste. Thus the man who fetches water cannot wait at table, nor the man who cooks the dinner serve it up; neither will the person who attends the table sweep the room afterwards—and so on through all the different pursuits of life. A native embracing Christianity loses caste by partaking of the Lord's Supper; it requires, therefore, great fortitude of mind to make a profession of faith in the gospel. There are many who have no caste, having been excommunicated because of some breach of the ceremonial laws of their religion, either by themselves or their forefathers; these are all termed Pariahs, and dare not touch the person, garments, food, utensils, or dwelling of a Hindoo of caste, as contamination follows. The Brahmins are a very lordly, domineering race, and exact the most severe homage of the Soodras. They themselves are under great restrictions, as well as the Soodras, particularly in the article of food, being prohibited from eating anything that has had life, except fish. This probably arises from their belief in the doctrine of transmigration; and as they believe

that although the spirits of their ancestors may have entered the bodies of all beasts, birds, reptiles, and insects, yet they do not enter into another element, so that they may eat fish with impunity. Rice, with spices, milk, and ghee, or clarified butter, is their principal diet, although they may partake of the flesh of such animals as are offered in sacrifice to the gods, the laws of the religion permitting this.

The Brahmins though all eligible to the priesthood, yet do not all follow it. Some enter the military service of the East India Company, and others become clerks and copyists; but none are permitted to engage in menial employments; and in whatever state they are found, the same honour is paid by their associates, though perhaps not to that degree as if in priestly office. So great is the pride of the Brahmins, that they claim precedence of kings, and the noblest rajah will partake of food cooked or presented by a Brahmin, whilst the meanest Brahmin will not taste that which has been prepared by a Soodra, although that Soodra should occupy a much higher station, civilly, than himself. The religion which inculcates these arrangements is found to be almost unconquerable by Christian missionaries, for the adoption of Christianity involves a total change of opinion on the constitution of society; and it is a melancholy fact that few except the worst of the Hindoo populace will become proselytes. It is now generally acknowledged, that in order to make any impression on the religion of the Hindoos, it will be absolutely necessary to commence with the instruction of the young in various branches of useful knowledge, to which happily the Brahmins offer no objection, while such instruction is universally desired by the people.

### BOODHISM.

Boodhism, or the religion of Boodh or Bhud, is considerably elevated above either pure paganism or Hindooism, and is deeply interesting from being the most prevalent form of religion upon earth. The number of the whole human race being estimated at 965,000,000, nearly the one-half, or 400,000,000, are Boodhists. According to the account of Mr Howard Malcolm, in his 'Travels in the Burman Empire,' to whom we are indebted for the following particulars, Boodhism is professed by half of the population of China, Lao, Cochinchina, and Ceylon; all of Camboja, Siam, Burmah, Thibet, Tartary, and Loo-Choo; and a great part of Japan, and most of the other islands of the southern seas, are of this faith. In some parts of Hindoostan it is the great rival of Hindooism; but its principal stronghold is in the adjoining empire of Burmah.

'Boodh' is a general term for divinity, and not the name of any particular god. There have been innumerable Boodhs, in different ages, among different worlds, but in no world more than five, and in some not any. In this world there have been four Boodhs—Kankathan, Gaunagong, Kathapa, and Gaudama. There is another yet to follow—namely, Aree-madayeh.

Gaudama.

It has often been supposed that Boodhism resembles Brahminism or Hindooism, which is a great mistake. No two systems can be more opposite, or bear less evidence of being derived from each other. Brahminism has incarnations, but Boodhism admits of none, for it

## CHAMBERS'S INFORMATION FOR THE PEOPLE.

has no permanent god. That has a host of idols; this only one. That enjoins bloody sacrifices; this forbids all killing. That requires atrocious self-tortures; this inculcates fewer austerities than Catholicism. That makes lying, theft, and other vices sometimes commendable, and describes the gods as excelling in these enormities; this never confounds right and wrong, and never excuses any sin. That makes absorption into deity the supreme good; this annihilation. In fine, I know of no important resemblance.

Boodhism inculcates no principle of caste, which is a striking difference from what prevails among the Hindoos; and from this and other causes it is believed to be much more ancient as a religion than Brahminism. The probability seems to be, that Brahminism grew out of Boodhism, and gained power and numbers in Hindoostan till the close of the first century of the Christian era, when the Brahmins were able to commence that persecution of which their own records speak, and which drove out the teachers of Boodhism into Farther India, whence it extended into China.

The most extraordinary peculiarity of Boodhism is the want of any existing God. Adoration or respect is merely paid to the image of Gaudama, who was a god at a former period, but is now annihilated, or entered into annihilation. Gaudama was the son of a king, and born about 626 years before the commencement of our era. He had previously lived in four hundred millions of worlds, and passed through innumerable conditions in each. In *this* world he had been almost every sort of worm, fly, fowl, fish, or animal, and in almost every grade and condition of human life. Having in the course of these transitions attained immense merit, he at length was born son of the above-named king. The moment he was born, he jumped upon his feet, and spreading out his arms, exclaimed, "Now am I the noblest of men! This is the last time I shall ever be born!" His height, when grown up, was nine cubits. His ears were so beautifully long, as to hang upon his shoulders; his hands reached to his knees; his fingers were of equal length; and with his tongue he could touch the end of his nose! All which are considered irrefragable evidences of his divinity.

When in this state his mind was enlarged, so that he remembered his former conditions and existences. Of these he rehearsed many to his followers. Five hundred and fifty of these narratives have been preserved—one relating his life and adventures as a deer, another as a monkey, elephant, fowl, &c. &c. The collection is called *Dzat*, and forms a very considerable part of the sacred books. These legends are a fruitful source of designs for Burman paintings. Of these I purchased several, which do but bring out into visible absurdity the system they would illustrate.

He became Boodh in the thirty-fifth year of his age, and remained so forty-five years, at the end of which time, having performed all sorts of meritorious deeds, and promulgated excellent laws far and wide, he obtained "nic-ban;" that is, entered into annihilation, together with five hundred priests, by whom he had been long attended. This occurred in Hindoostan about 2380 years ago, or B.C. 546. At his death he advised that, besides obeying his laws, his relics and image should be worshipped, and pagodas built to his memory, till the development of the next Boodh. He is invariably represented in the same manner, except that sometimes he is made to wear a crown, necklace, ornaments on his arms, &c. I have seen them of all sizes, from half an inch long to seventy-five feet—of wood, stone, brass, brick, clay, and ivory.

The next Boodh is to appear in about seven or eight thousand years from the present time. His height will be eighty cubits, his mouth will be five cubits wide, and the length of the hairs of his eyebrows five cubits. The precise time of his arrival is not predicted. No laws or sayings of the first three Boodhs are extant. Those of Gaudama were transmitted by tradition, till 450 years after his decease, when they were reduced to writing in Ceylon—that is, A.D. 94. These

are the only sacred books of the Burmans, and are all in the Pali language. They are comprised in three divisions, each of which is divided into distinct books or sections. The whole is called the *Bedagat*.

According to the *Bedagat*, the universe consists of an infinite number of systems: each system consists of a great central mountain surrounded by seas, and four great islands, each surrounded by five hundred smaller ones. This earth is in the southern cluster of islands, and we are living on the larger one. It is a convex plane, not a sphere; and is divided by mountains and navigable seas. Below its upper crust, on which we live, is water twice as deep as the earth is thick. The whole is supported on a stratum of air twice as deep as the water. Beneath is a vacuum. The celestial regions consist of twenty-six principal heavens, one above another; and the infernal regions of eight principal places of punishment, each surrounded by sixteen smaller ones. In one of the heavens there are pleasant habitations for mortals after death; and at the king's principal residence there is an elephant of stupendous size. This animal is of immense height, and has seven heads; each head has seven tusks, and each tusk seven tanks. In each of these tanks grow seven lilies; each lily has seven blossoms; each blossom has seven petals; each petal bears up seven palaces, and in each palace are seven nymphs, or wives of the king, each surrounded by 500 attendants. Another elephant has one great head, thirty uzenas long, on which the king occasionally rides; and thirty-two smaller heads, for the thirty-two royal princes. Of the principal hells, four inflict punishment by heat, and the other four by cold.

Not only has the universe and all its systems existed from eternity, but also the souls of all the inhabitants, whether animals, men, or celestials. These souls have from eternity been transmigrating from one body to another, rising or falling in the scale of existence and enjoyment, according to the degree of merit, at each birth. This rise or fall is not ordered by any intelligent judge, but is decided by immutable fate. In passing through these various forms of existence, the amount of sorrow endured by each soul is incalculable. The *Bedagat* declares that the tears shed by any one soul, in its various changes from eternity, are so numerous, that the ocean is but a drop in comparison! Existence and sorrow are declared to be necessary concomitants; and therefore "the chief end of man" is to finish this eternal round of changes, and be annihilated.

The great doctrines of this faith are five—namely, 1. The eternal existence of the universe, and all beings. 2. Metempsychosis. 3. Nic-ban, or annihilation. 4. The appearance, at distant periods, of beings who obtain deification and subsequent annihilation. 5. The obtaining of merit. Of the first four of these enough has been already said. The last is more deserving of notice, embracing as it does the whole system of morals.

Merit consists in avoiding sins and performing virtues, and the degree of it is the sole hope of the Boodhist. The sins which are to be avoided are described in a moral code, consisting of five principal and positive laws:—1. Thou shalt not kill. 2. Thou shalt not steal. 3. Thou shalt not commit adultery. 4. Thou shalt not lie. 5. Thou shalt not drink any intoxicating liquor. These are explained and branched out, so as to include all sins of the same kind under each head. The first of these laws is extended to all killing, even that of animals for food. The strictly religious will not take the life even of vermin. War and capital punishments are considered forbidden by the first law.

Sins are divided into three classes:—1. Those of the body—such as killing, theft, &c. 2. Those of the tongue—as falsehood, discord, harsh language, idle talk, &c. 3. Those of the mind—as pride, covetousness, envy, heretical thoughts, adoring false gods, &c. The sacred books portray strongly the evils of pride, anger, covetousness, and inordinate appetites. Men are urged to avoid excessive perfumes, ornaments, laughter, vain joy, strong drink, smoking opium, wandering about the streets in the night, excessive fondness for amusements,

## PAGAN AND MOHAMMEDAN RELIGIONS.

frequenting bad company, and idleness. Those who aspire to *nic-ban* are cautioned to abhor sorcery, not to credit dreams, not to be angry when abused nor elated when approved, not to flatter benefactors, not to indulge in scorn or biting jests, and most carefully to avoid unkind strife and hatred.

The states of the mind are resolved into three classes:—1. When we are pleased in the possession of agreeable things. 2. When we are grieved and distressed by evil things. 3. When neither do good things gratify us, nor evil things distress. The last is the best state, and in it a man is rapidly preparing for *nic-ban*. In this there is no small resemblance to the doctrine of the Stoics, and some approach to the Christian doctrine of weanedness from the world. Some of their books abound in good comparisons, such as, that he who runs into sinful enjoyments is like a butterfly who flutters round a candle till it falls in; or one who, by licking honey from a knife, cuts his tongue with the edge. There is scarcely a prohibition of the *Bedagat* which is not sanctioned by our Holy Scriptures, and the arguments appended to them are often just and forcible.

Merit is of three kinds:—1. *Theela*, or the observance of all the prohibitions and precepts, and all duties fairly deducible from them; such as beneficence, gentleness, integrity, lenity, forbearance, condescension, veneration for parents, love to mankind, &c. &c. 2. *Dana*, or giving alms and offerings. This includes feeding priests; building *kyoungs*, pagodas, and *zayats*; placing bells at pagodas; making public roads, tanks, and wells; planting trees for shade or fruit; keeping pots of cool water by the wayside for the use of travellers; feeding criminals, birds, animals, &c. 3. *Bawana*, or repeating prayers, and reading religious books.

Alms-deeds are meritorious according to the objects on which they are bestowed, and proportioned to the following scale:—1. Animals. 2. Common labourers, fishermen, &c. 3. Merchants and the upper classes, when in necessity. 4. Priests. For alms of the first class, the rewards are long life, beauty, strength, knowledge, and prosperity, during a hundred transmigrations; for those of the second class, the same during a thousand transmigrations; for the third, the same during ten thousand; for the fourth, a greater number, but indefinite, being graduated according to the degree of sanctity the particular priests may possess.

Many discourses said to have been delivered by *Gaudama* are given in the *Bedagat*. In these, the duties of parents, children, husbands, wives, teachers, scholars, masters, slaves, &c. are drawn out and urged in a manner which would do honour to any casuist.

The following is part of one of these discourses, addressed to a distinguished personage, who sought his instruction how to avoid evil:—

“Know thou, that to keep from the company of the ignorant, and choose that of learned men; to give honour to whom it is due; to choose a residence proper to our station, and adapted for procuring the common wants of life; and to maintain a prudent carriage, are means to preserve a man from evil doings. The comprehension of all things that are not evil, the exact knowledge of the duties of our station, and the observance of modesty and piety in our speech, are four excellent modes of renouncing wickedness.

By ministering a proper support to parents, wife, and family, by purity and honesty in every action, by alms-deeds, by observing the divine precepts, and by succouring relations, we may be preserved from evil. By such a freedom from faults, that not even the inferior part of our nature manifests any affection for them, by abstinence from all intoxicating drink, by the continual practice of works of piety, by showing respectfulness, humility, and sobriety before all, and gratitude to our benefactors; and finally, by listening often to the preaching of the word of God, we overcome evil inclinations, and keep ourselves far from sin. Docility in receiving the admonitions of good men, frequent visits to priests, spiritual conferences on the divine laws, patience, frugality, modesty, the literal observance of

the law, keeping before our eyes the four states into which living creatures pass after death, and meditation on the happy repose of *nic-ban*—these are distinguished rules for preserving man from wickedness.”

Pagodas are innumerable. In the inhabited parts there is scarcely a mountain peak, bluff bank, or swelling hill, without one of these structures upon it. Those of Pegu and Siam are all formed upon one model, though the cornices and decorations are according to the builder's taste. In general they are entirely solid, having neither door nor window, and contain a deposit of money, or some supposed relic of *Gaudama*. From the base they narrow rapidly to about mid-way, and then rise with a long tapering spire, surmounted with the sacred tee. Some of the pagodas around *Ava*, and especially those at *Paghan*, are less tapering, and more resembling ordinary temples.

*Zayats* are not exclusively religious buildings. Some are intended to contain idols, and some are for the accommodation of worshippers and travellers, and for town-halls. The majority contain no idols, and are intended only to afford shelter for worshippers and travellers. Some of these are mere sheds, open on all sides; but in almost all cases they are built in a far more durable and costly manner than dwelling-houses.

Every village has a *zayat*, where the stranger may repose or stay for many days, if he please; and many a time I found them a comfortable lodging-place. Like the chultries of Hindoostan, they are of unspeakable utility in a country destitute of inns, and where every house has its full complement of inmates. Many *zayats*, especially near great cities, are truly beautiful, and very costly. The ceilings and pillars are not only elaborately carved, but completely gilded, and the stucco floors rival marble in hardness and polish.

Worship is not performed collectively, though crowds assemble at the same time on set days. Each one makes his offerings and recites his prayers alone. No priests officiate; no union of voice is attempted. On arriving at the pagoda, or image, the worshipper walks reverently to within a convenient distance, and laying his offering on the ground, sits down behind it, on his knees and heels, and placing the palms of his hands together, raises them to his forehead, and perhaps leans forward till his head touches the ground. This is called the *sheeko*. He then utters his prayers in a low tone, occasionally bowing as before; and having finished, rises and carries forward his gift, laying it somewhere near the idol or pagoda. Some proceed first to one of the great bells which hang near, and strike several times with one of the deer's horns which always lie beneath. When one goes alone, this is seldom omitted. There are four set days in every lunar month on which the people assemble in greater numbers at the pagodas to offer their individual prayers. These days are at the new and full moon, and seven days after each; so that sometimes their Sabbath occurs after seven days, and sometimes after eight.

Boodhist priests are not a caste or hereditary race. Any one may become a priest, and any priest may return to a secular life at pleasure. Thousands, in fact, return every year, without the least reproach. On becoming a priest, a yellow robe is assumed, and celibacy, with numerous mortifications, is enjoined. Their office may be called a sinecure, as they seldom preach or perform any service, except teaching and giving special religious advice. They are of different degrees of rank, and subsist entirely on the contributions of the people. Their number is very great. *Ava*, with a population of about 200,000, is said to contain nearly 20,000 priests.

In point of moral obligation, and the inculcation of purity of life, Boodhism is infinitely superior to Hin-

Boodhist Priest.

## CHAMBERS'S INFORMATION FOR THE PEOPLE.

deceit. It has no mythology of obscene and ferocious deities, no sanguinary or impure observances, no self-inflicted tortures, no tyrannising priesthood, no confounding of right and wrong, by making certain iniquities laudable in worship. In its moral code, its descriptions of the purity and peace of the first ages, of the shortening of man's life because of his sins, &c. it seems to have followed genuine traditions.

At the same time, we must regard Boodhism with unmeasured reprobation, if we compare it, not with other false religions, but with truth. Its entire base is false. It is built, not on love to God, nor even love to man, but on personal merit. It allows evil to be balanced with good, by a scale which reduces sin to the shadow of a trifle. To sheeko to a pagoda, or offer a flower to the idol, or feed the priests, or set a pot of cool water by the wayside is supposed to cancel a multitude of sins. The building of a kyoung or pagoda will outweigh enormous crimes, and secure prosperity for ages to come. Vice is thus robbed of its terrors, for it can be overbalanced by easy virtues.'

### LAMAISM.

In Thibet, Tartary, and other parts of Central Asia, inhabited by the Mongolian race, Boodhism assumes a different form and name, being more a religion of pure priestcraft and external observance, and including a belief in the continual personal presence of a supreme God. This branch of Boodhism, as it is believed to be, is usually called Lamaism, the word *Lama* literally signifying priest. Like Boodhism, this religion acknowledges no eternal, self-existent being. The idols, to the number of 108, are representatives of created beings, who ascended into the rank of gods before the present world was created, on account of their holiness. The chief god is Shigemooni, who appeared in the world for the last time a thousand years before the Christian era, and then instituted Lamaism, with a visible living representative of himself, called Dalai-Lama, or the Great Lama. The worship of this Grand Lama, therefore, is a principal feature in the system of belief.

It is understood and inculcated, that when the Grand Lama expires in the course of nature, his spirit immediately takes possession of some other body in a supernatural manner, which it is impious to inquire into, and is only comprehended by the attendant priests. In point of fact, the religion which inculcates this absurdity is idol-worship under a different name, the idol being a living creature instead of an inanimate object, as in ordinary paganism; and the whole system seems to have been devised in order to support a numerous host of priests and religious establishments.

Dalai-Lama, or the Grand Lama, is at the head of both ecclesiastical and secular affairs in Thibet, which may be considered a theocratical state. The usual residence of the Dalai-Lama is in two monasteries situated in the vicinity of the capital, Lassa, in each of which he dwells alternately. He is surrounded in every direction by a vast number of priests; but no woman is permitted to pass the night in the building where he lodges. This arises undoubtedly from the purity which is attributed to him, for he is called the *immaculate*. The natives, as well as a great crowd of foreigners (for all the Mongol tribes in Russia acknowledge him), undertake fatiguing pilgrimages in order to pay their homage to him, and obtain his blessing. He receives them sitting upon a kind of altar, upon a large and splendid seat, with his legs crossed. The Tartars, next to the inhabitants of Thibet, pay him the greatest reverence. They come to him from the most distant regions, and the princes, to whom he shows no more respect than to others, submit to the same ceremonies as their people. He salutes no one, never uncovers his head, rises up before no one, and is satisfied with laying his hand upon the head of his worshipper, who believes that he has thereby obtained the pardon of his sins. His worshippers believe that the supreme divinity lives in him, that he knows and sees everything in the deepest recesses of the heart, and never needs to make inquiry

in regard to anything. If he does this, it is only that unbelievers and the evil-minded may not have cause for complaint. He sometimes distributes, it is said, little balls of consecrated dough, which the Tartars use in many superstitious practices; but it is not true that balls made from his excrement are distributed, preserved in golden boxes, and even mixed with articles of food. His power was once greater than it is now, and he appointed and deposed the khans; but at present he is dependent on the emperor of China, although the latter, in a religious respect, is subjected to him. Two Chinese mandarins, with a garrison of 1000 Chinese, are maintained in his capital, and in the palace at Pekin the Chinese emperor supports a subordinate Lama, who is sent as a nuncio from Thibet.

When the Dalai-Lama dies, it is then necessary to discover where his spirit has chosen to be born anew. In this case all must submit to the opinion of some of the Lamas, who alone are acquainted with the signs by which he may be known, or, rather, who know what child the deceased has appointed for his successor. The worshippers of the Lama are divided, in general, into two sects, known by the titles of the *yellow* and *red caps*. Each sect is under three Lamas; the former is under the Dalai, Teeshoo or Bogao, and Taranaut Lamas; the latter, under the three shammas. The Dalai-Lama is the most distinguished of all, and next to him is the Teeshoo-Lama, who dwells at Teeshoo-Loomboo, ten days' journey from Lassa. The three shammas dwell in separate monasteries, the most distinguished of which is at Tassaudon, the capital of Bootan. Subordinate to them are numerous priests of different ranks, who are held in great respect, who superintend instruction, and some of whom live in a state of celibacy, according to certain rules similar to those of the Christian monks. At Lassa alone there are about three thousand monasteries.

### MOHAMMEDANISM.

The religion of Mahomet, or Mohammed, and called Mohammedanism, partakes of a much more exalted character than any of the mythological superstitions already adverted to, inasmuch as it approaches a pure theism, or a belief in the one true God. This famed religion, which now prevails in Arabia, Egypt, the Moorish states, Turkey, Persia, and is extended in a scattered manner over the countries of south-eastern Asia, and numbers, according to common belief, more than one hundred millions of followers, originated in Arabia at the beginning of the seventh century of the Christian era.

At this period, eastern countries were in a condition to receive a new and vigorously-conducted form of religious belief. The scattered branches of the Christian church in Asia and Africa were at variance with each other, and had adopted the wildest heresies and superstitions. They were engaged in perpetual controversies, and torn to pieces by the disputes of the Arians, Sabellians, Nestorians, and Eutyrians; whilst the simony, the incontinence, and general barbarism and ignorance which were to be found amongst the clergy, caused great scandal to the Christian religion, and introduced universal profligacy of manners amongst the people. While Christianity, in the manner it was abused by unenlightened followers, was of little avail in civilising the Asiatics, while the religion of the Jews was sunk into comparative insignificance, and while paganism still flourished in the East, Mohammedanism was introduced upon the scene, and in a wonderfully short period of time gave an entirely new cast to manners and form of belief. Arabia being the country in which this new religion was first promulgated, it is considered desirable to mention the nature of the religion which the people previously professed and now abandoned.

The ancient Arabs are supposed to have been what are termed pure theists—that is, they are supposed to have believed in and worshipped one sole, omnipotent, and everlasting God. Historians, however, have sel-

## PAGAN AND MOHAMMEDAN RELIGIONS.

dom correctly appreciated the meaning of these magnificent expressions in the mouth of a savage. In his mind such language is connected with ideas and feelings far other than those which a civilised man would express by it. These splendid epithets are the mere expressions of flattery and fear. The Deity now addressed, and whose favour is the object of present desire, is for the time the sole object of adoration. The very same savage, who believes in a host of gods, will address each of them by the term of THE ONE. If among many deities one is thought more powerful than the rest, he will be the oftenest addressed, the oftenest soothed by flattery. No epithet is so flattering as that which asserts his single existence. It exalts him above all beings, and leaves him without a rival. No epithet, therefore, will be so frequently employed. Being the most constantly adored, this more powerful divinity will have this epithet expressive of his sole existence so frequently connected with his name, that it will at length be regularly attached to, and form part of, that name. This was precisely the case with the Arabian objects of worship. It is certainly strange that, when complete evidence of this fact exists, really intelligent and circumspect historians should have believed in the pureism of the Arabians.

Mr Sale, like many others, was deceived by pompous expressions:—"That they acknowledged one supreme God, appears (to omit other proof) from their usual form of addressing themselves to him, which was this:—'I dedicate myself to thy service, O God!—I dedicate myself to thy service, O God! Thou hast no companion, except thy companion of whom thou art absolute master, and of whatever is his.'" In the very next passage, however, Sale adds, "They offered sacrifices and other offerings to idols, as well as to God, who was also often put off with the least portion, as Mohammed upbraids them." Their scheme of divine government was simple, and like most others formed in the same state of civilisation. One god was supposed to be the supreme ruler; and subject to his sway was a vast multitude of inferior deities. "The Arabs acknowledged one supreme God, the creator and lord of the universe, whom they called Allah Taala, the most high god; and their other deities, who were subordinate to him, they called simply Al Ilahat, that is, goddesses." Idols were set up and worshipped; every field, every rivulet, had its divinities. The fixed stars and planets were also exalted into gods, and as such received adoration. Heaven, moreover, was peopled with angels, who, with the wooden, stone, and clay idols on earth, were regularly worshipped. How the Arabians can be supposed believers in a single godhead, under such circumstances, appears extraordinary.

The manner in which these various divinities were rendered propitious, at once determines the fact that no very exalted conception of a divinity existed in the minds of these barbarians. Fasts, pilgrimages, sacrifices, long and unmeaning prayers, were the means employed to obtain the divine favour.

"They are obliged," says Sale, "to pray three times a-day (some say seven times a-day): the first, half an hour or less before sunrise, ordering it so that they may, just as the sun rises, finish eight adorations, each containing three prostrations; the second prayer they end at noon, when the sun begins to decline, in saying which they perform five such adorations as the former; and the same they do the third time, ending just as the sun sets. They fast three times a year: the first thirty days, the next nine days, and the last seven. They offer many sacrifices, but eat no part thereof, but burn them all. They abstain from beans, garlic, and some other pulse and vegetables."

"The same rites," says a recent writer, "which are now accomplished by the faithful Mussulman, were invented and practised by the superstition of the idolaters. At an awful distance they cast away their garments; seven times, with hasty steps, they encircled the Caaba, and kissed the black stone; seven times they visited and adored the adjacent mountains; seven times they

threw stones into the valley of Mina, and the pilgrimage was achieved, as at the present hour, by a sacrifice of sheep and camels, and the burial of their hair and nails in the consecrated ground." The Arabians had many other superstitious practices; they held their women in a degraded condition; and, though refined in some points of manners, they had no written law, were governed despotically by chiefs, and were really barbarians and idolaters. It was the debased religion of this people which Mohammed designed to improve, and we have now to see who this bold and ingenious man was, and how he carried his plans into execution.

Mohammed was born at Mecca, the capital city of Arabia Felix, A. D. 569, during the reign of Noosheervan, surnamed the Just, king of Persia. He was of the family of Haschem, and of the tribe of the Koreish, the noblest in Arabia. His father Abdallah was a younger son of Abdalmotaleb, and dying very young, and in his father's lifetime, left his widow and infant son in very mean circumstances, his whole substance consisting but of five camels and one Ethiopian female slave. Abdalmotaleb was therefore obliged to take charge of his grandchild Mohammed, which he not only did during his life, but at his death ennobled his eldest son, Abu Taleb, who was brother to Abdallah by the same mother, to provide for him for the future. This was very affectionately performed by Abu Taleb, who instructed him in the business of a merchant, which he followed; and to that end he took young Mohammed into Syria when he was but thirteen years old, and afterwards recommended him to Khadijah, a noble and rich widow, for her factor, in whose service he behaved so well, that, by making him her husband, she soon raised him to an equality with the richest in Mecca.

It was after he began, by this advantageous match, to live at his ease, that he formed the scheme of establishing a new religion, or, as he expressed it, of replanting the only true and ancient one professed by Adam, Noah, Abraham, Moses, Jesus, and all the prophets, by destroying the gross idolatry into which the generality of his countrymen had fallen, and weeding out the corruptions and superstitions which the latter Jews and Christians had, as he thought, introduced into their religion, and reducing it to its original purity, which consisted chiefly in the worship of one only God. He hereupon began to affect solitude, usually retiring for a month in the year to a cave in Mount Hara, near Mecca. He had indisputably a very piercing and sagacious intellect, and was thoroughly versed in all the arts of inauination. The eastern historians describe him to have been a man of an excellent judgment and a happy memory; and these natural parts were improved by a great experience and knowledge of mankind, and the observations he had made in his travels. He is represented as a man of few words, of an equal, cheerful temper, pleasant and familiar in conversation, of inoffensive behaviour towards his friends and acquaintances, and of great condescension towards his inferiors; to all which were joined a comely, agreeable person, and a polite address—qualities of no small service in prepossessing those in his favour whom he attempted to persuade and govern.

'When the prophet was about four years old,' says Mahmut the Arabian, 'accompanying the sons of his nurse into the field, the blessed child retired into a cave, at the foot of the mountain Uriel, to pray, when the Archangel Gabriel appeared to him, and said, *Bismilliarrahmanirrahimi*; that is, "In the name of God, compassionate and merciful, oh child greatly beloved, I am sent to displant from thy heart the root of evil; for thy ejaculations made the gates of Paradise to fly open!" The young resigned one said, "The will of thy Lord and mine be done." Then the angel opened his breast with a razor of adamant, and, taking out his heart, squeezed from it the black contagion which was derived from Adam; and having put the child's heart in its place again, he blessed him, and retired to the invisibles. From that time the young favourite of Heaven grew

up and prospered in all things, having the smiles of God and man. He was under the tuition of his uncle Abu Taleb, who, discerning the mark of an immense soul in his young nephew, was more solicitous for his welfare than if he had been his son. His fortune being low in the world, he had no other way to provide for his illustrious charge than by placing him as a factor to Khadijah, a widow of the same tribe with Mohammed, which was the noblest among the Arabians.'

Mohammed's marriage with Khadijah took place when they were respectively twenty-five years of age; and it was not till twelve years after this marriage that he began to fabricate his imposture, in the cave of Mount Hara, about three miles from Mecca, to which he usually retired during the month of Ramazan, being the time of Lent. At length, A.D. 609, when he was fully forty years old, he disclosed his prophetic mission, at first only to his own wife Khadijah. He told her that the angel Gabriel had appeared to him in glory, and declared that God had commissioned him as an apostle to reform the world; *that he then delivered to him the Koran for a Divine law, which should complete all antecedent revelations.* Khadijah gained for her husband an important proselyte in her uncle Waraka, a Christian, who was well read in the Old and New Testaments. He pronounced Mohammed 'to be the great prophet foretold by Moses the son of Amram.' It is much more probable that Waraka was the assistant of Mohammed in composing the Koran than Sergius the monk, or any other person.

The next proselyte was Abubeker, a rich and respectable inhabitant of Mecca; and his example being followed by many others, Mohammed ventured on a bolder demonstration of his mission. At a numerous assemblage of the Koreishites, at a public entertainment to which he had invited them, he demanded who would become his vizier, or prime minister, assuring them that both happiness in this world and in that to come would accrue to his followers. The guests remained silent in surprise, when Ali, the son of Abu Taleb, a boy about fourteen years of age, started up enthusiastically, and said, 'I will be thy vizier, oh Prophet of God! I will break the teeth, pluck out the eyes, rip up the belly, cut off the legs of thine enemies.' The joy and approval testified by Mohammed to the zeal of his youthful disciple, was an apt and early specimen what manner of spirit he and his deputy were of.

The hostile proceedings and denunciations of the prophet against their idolatry, at length aroused the enmity of the Koreishites; but their threats were despised by him, and, in reply to the prudent remonstrances of his uncle Abu Taleb, he exclaimed, 'Though the Koreishites should arm against me the sun and the moon (alluding to the divinities whom they ignorantly worshipped), the one on my right hand, and the other on my left, I would not be shaken from my resolution.' He, however, retired for a while to a castle in Mount Safa, and his followers were banished from the city of Mecca. After this persecution, which lasted five years, in the tenth year of his mission (A.D. 618), he sustained a serious loss in the death of his uncle Abu Taleb; and this was followed a short time after by the death of his affectionate wife Khadijah, who had so generously made his fortune. On account of these misfortunes, this year was called the Year of Mourning. Instead of sinking under these adversities, however, upon being violently urged by the Koreishites, who still derided his pretensions, to exhibit some miracle worthy of their belief, Mohammed ventured, in the twelfth year of his mission, to publish the revelation of his night visit or journey to the seven heavens.

This event formed a striking epoch in his mission, and displayed in the strongest manner the dexterity as well as boldness of his measures. The question so forcibly put to him of establishing his mission by miracles, is therein artfully parried, and replied to by an appeal to the wonders wrought by Moses, which did not cause the reformation of Pharaoh, and to those of Jesus, which failed with the Jews; he also incidentally re-

marked, that miracles were designed rather to strike terror and to punish than to convince.

This famous journey is thus described by Mohammed: While he was in the Caaba, or sacred square building at Mecca, reclining on the sacred stone, the angel Gabriel came to him; he opened his breast, took out his heart, and washed it in a golden basin full of the water of *faith*, and then restored it to its place. The angel had seventy pairs of wings, and had the beast Alborak with him, on which the prophets used to ride; it was white, and partly horse, ass, and mule, or a middle between the two last, and went as fast as the lightning, which the name Alborak, in Arabic, signifies. When he was brought to Jerusalem by the angel, all the prophets met him, and owned his superiority. He ascended to heaven with the angel, on a ladder of divine light, and left the beast Alborak at Jerusalem till he descended again. He went through seven heavens before he came to the throne of God, which was in the last one, and Gabriel left him at the entrance of it, and waited till he returned from conversing with God, who gave him the offer to be next himself; but he rather chose to descend again to the earth to propagate his religion. His heavens were all 500 years' journey distant from one another. One was of silver, another of gold, another of emerald, &c. and the last of light. He met some one of the patriarchs or prophets in each of them. In the first he met and discoursed with Adam; in the second, with John the Baptist and Jesus; in the third, with the patriarch Joseph; in the fourth, with Edris or Enoch; in the fifth, with Aaron; in the sixth, with Moses; in the seventh, with Abraham. Thence he was carried up to *Sedrat*, the lotus tree, whence were the sources of the four rivers of Paradise. He saw angels in the likenesses of all creatures in these heavens. He saw a great bull bearing the earth on his horns, and when he shook his head there was an earthquake. There was also a cock, which stood on one heaven, and his head reached another; his voice was heard through heaven and earth, and set all the cocks on earth crowing. He saw an angel of such stature that there was 70,000 days' journey between his eyes. The proportion of a man's height to the distance between his eyes is as seventy-two to one; so that his stature must then have been 14,000 years' journey, four times the height of all his heavens together, in which he was quite out of his mathematics. In the seventh heaven, where God and Christ were, was an angel with 70,000 heads; and in each head 70,000 tongues, with which he praised God. Gabriel accompanied him down from heaven to Jerusalem, and from thence conveyed him, with the beast Alborak, to Mecca; and all this was done in the tenth part of a night. In the conclusion of this extraordinary fabrication, he skillfully adds, that when he was enjoined to repeat fifty prayers each day, he intreated for his nation, and they were finally reduced at his intercession to five. To finish the wonder, he was returned back to the Caaba ere the crier called him to prayers; and 'thus,' concluded Mohammed, 'did I bring with me the prescribed number of prayers, and lessened the burden for my nation.'

This story seemed so absurd and incredible, that several of his followers left him on account of it; and it had probably ruined the whole design, had not Abubeker vouched for his veracity, and declared that, if Mohammed affirmed it to be true, he verily believed the whole; which happy incident not only retrieved the prophet's credit, but increased it to such a degree, that he was secure of being able to make his disciples swallow whatever he pleased to impose on them for the future. 'And I am apt to think,' says Sale, 'this fiction, notwithstanding its extravagance, was one of the most artful contrivances Mohammed ever put in practice, and what chiefly contributed to the raising of his reputation to that great height to which it afterwards attained.'

In this memorable year twelve citizens of Medina swore allegiance and obedience to the Prophet, whence they were styled, by way of dignity, *Al Ansar*—that is,

## PAGAN AND MOHAMMEDAN RELIGIONS.

'The Defenders;' and the year A.D. 620 was denominated the 'accepted year.' On Mount Akaba, near Mecca, seventy-three proselytes were soon after added to their number, and swore to defend the prophet from all insult, as they defended their own wives and children. 'If,' said they to the apostle of God, 'we be slain in thy cause, what shall be our reward?' He answered 'Paradise.' 'Then,' said they, 'Stretch forth thy right hand,' and he did so; then they took the oath of obedience, promising rather to die than be perjured. Mohammed now established twelve apostles of Islamism, which was the name he gave to his religion, himself being the prime instructor and chief of all the true believers; and he then sent away the Ansars, his followers, and his family, to Medina, for security, and remained behind at Mecca, attended only by Abubeker and his son-in-law Ali.

By the protection which his uncle Abu Taleb had extended to Mohammed, he had been preserved thus far from his enemies; but the charge and dignity of the priest and guardian of the Kaaba having now, by the death of Abu Taleb, become the post of a member of the family of Ommyyah, a declared enemy to the family of Haschem, to which Mohammed belonged, the Koreishites, irritated and alarmed at the progress making by the new doctrine at Medina, resolved to destroy its author and chief support. This conspiracy was scarce formed, when, by some means or other, it came to Mohammed's knowledge, and he gave out that it was revealed to him by the Angel Gabriel, who had now ordered him to retire to Medina. Whereupon, to amuse his enemies, he directed Ali to lie down in his place, and wrap himself in his green cloak, which he did; and Mohammed escaped miraculously, as they pretend, to Abubeker's house, unperceived by the conspirators, who had already assembled at the prophet's door. They, in the meantime, looking through the crevice, and seeing Ali, whom they took to be Mohammed himself, asleep, continued watching there till morning, when Ali awoke, and they found themselves deceived.

In the recesses of a cave near Mecca, Mohammed and Abubeker eluded for three days the pursuit of their enemies. 'There are only two of us,' said the apprehensive disciple, when he expected the pursuers to penetrate their retreat. 'There is a third, even God himself,' said his intrepid chief; 'he will defend us.' According to tradition, Mohammed afterwards asserted that a miracle was here wrought in his behalf; for that his enemies, approaching the cave, found that its entrance was covered by spiders' webs hanging from the trees, which convinced them that no person had entered it for a long time. After a perilous journey, Mohammed entered Medina in triumph, being enthusiastically received by the Ansars, who disputed for the honour of entertaining the prophet, and took hold of the bridle of his camel. Mohammed then desired them to let her take her own way, for she was a stubborn beast; which she took accordingly, and stopped at the stable of two rich orphans, Sahali and Sohaili, where the prophet dismounted. This spot he purchased from the orphans, after refusing their offer to bestow it upon him, and Abubeker paid the money. He erected thereon a mosque, and a habitation for himself, at which he is said to have laboured with his own hands. Medina henceforth received the august title of *Medinat al Nabi*, or the 'City of the Prophet.'

The Mohammedan era, called the Hejira, takes its commencement from the date of Mohammed's flight from Mecca to Medina. The generality of writers place this epoch on Friday the 16th of July, A.D. 622. It is this event which has rendered Friday the solemn day of the week for his followers; this choice also agreeing with the customs of the Arabians, who held their assemblies usually on the Fridays. The word *Hejira* is derived from the Arabic verb *Hajara*, to abandon one's native country, to emigrate on account of persecution; which comes from the Hebrew *Hugar*, the stranger or emigrant, the name of Ishmael's mother.

It was from this period that Mohammed, having fully

ascertained the hate of his enemies, and the extent of his own power, proceeded to lay aside the arts of persuasion and patient endurance, whereby he had hitherto sought to propagate his tenets; and elated by the devotion of his disciples and his reception at Medina, he framed henceforth the revelations of the Koran in a tone which proclaimed him a persecutor, and empowered his followers to make war against all opposers. The successful battle of Beder followed soon after; and he then made known those doctrines which have rendered the arms of the Mussulmans so formidable—namely, 'that no one can escape his destiny; inasmuch as the man whose days are not complete, will escape unhurt from a shower of arrows, when he whose fatal term has arrived, cannot escape death by any precaution whatsoever.' The second incitative is that which the present occasion furnished him with:—'The sword,' exclaimed the prophet, 'is the key of heaven and of hell; a drop of blood shed in the cause of God, a night spent *untier arms*, is of more avail than two months of fasting and prayer. Whosoever falls in battle, his sins are forgiven: at the day of judgment his wounds shall be resplendent as vermillion, and odoriferous as musk; the loss of his limbs shall be replaced by the wings of angels and of cherubim.'

This victory, the first of Mohammed's battles, was gained, in the second year of the Hejira, over the idolatrous Meccans, headed by Abu Sofian, in the valley of Beder, which is situated near the sea, between Mecca and Medina. Mohammed's forces consisted of no more than 319 men, and the enemy's army of near 1000; notwithstanding which odds, he put them to flight, having killed seventy of the principal Koreish, and taken as many prisoners, with the loss of only fourteen of his own men. This first victory, although it may seem no very considerable action, was yet of great advantage to him, and the foundation of all his future power and success; for which reason it is very famous in Mohammedan history, and is frequently vaunted of in the Koran as an effect of the Divine assistance, through the miraculous interposition of the Angel Gabriel. The gaining of the battle was, however, wholly attributable to the extraordinary stratagem of Mohammed, by his expedient, at the critical moment, of scattering a handful of dust against his enemies, at the same time exclaiming, 'Let their faces be confounded!'—which action so invigorated his fainting followers, that they charged and overthrew their foes. Mohammed captured the whole caravan, which consisted of 1000 camels, richly laden, from Syria; and this afforded him the means of rewarding his followers, and inciting them to further exertion by the allurements of wealth and the hope of plunder.

Some reckon as many as twenty-seven expeditions wherein Mohammed was personally present, in nine of which he gave battle; besides several other expeditions, undertaken by his orders, in which he was not present. His forces he maintained partly by the contributions of his followers for this purpose, which he called by the name of *zacaat*, or alms, and the paying of which he very artfully made one main article of his religious system; and partly by ordering a fifth part of the plunder to be brought into the public treasury for that purpose, in which matter he likewise pretended to be guided by the Divine direction.

In a few years, by the success of his arms, he considerably raised his prophetic character and power. In the sixth year of the Hejira, he set out with 1400 men to visit the temple of Mecca, not with any intention of committing hostilities, but in a peaceable manner. However, when he came to Al Hodeibiya, which is situated partly within and partly without the sacred territory, the Koreish sent to let him know that they would not permit him to enter Mecca unless he forced his way; whereupon he called his troops about him, and they all took a solemn oath of fealty or homage to him, and he resolved to attack the city; but those of Mecca, sending Arwa Ebn Masud, prince of the tribe of Thakif, as their ambassador, to desire peace, a truce was concluded between them for ten years, by which

any person was allowed to enter into league either with Mohammed or with the Koreish, as he thought fit.

Having subdued the chief part of the pagan tribes, and by his relentless severity exterminated the Jewish classes who dwelt peaceably in Arabia, in the seventh year of the Hejira (A.D. 628), he assumed the state of a sovereign, and sent embassies to the neighbouring monarchs, exhorting them to embrace Islamism.

In the eighth year of the Hejira, a quarrel, real or feigned, gave him the opportunity of possessing himself of Mecca, and of the sacred square edifice called the Caaba. Mohammed appearing suddenly at their gates with 10,000 men, before the troops of Mecca had even been apprised of his departure from Medina, they had no choice left but an immediate surrender or destruction. Thus pressed, and menaced with instant death, the Koreish submitted to the superior power of Mohammed. Their final submission to him, and their acceptance of his faith, were ratified subsequently on the hill El Safa. Having visited the holy building of the Caaba, and broken in pieces the idols wherewith it was encircled, Mohammed went in procession seven times round the building, and touched respectfully the black stone which was held sacred by the Arabs; then entering the edifice, he repeated the formulary, '*God is great.*' Afterwards he went to the well Zemzem—which is believed by them to be the same that the angel showed to Hagar—drank of the water, and performed the required ablution. Artfully blending attention to exterior observances with zeal, and pursuing a mixed system of mercy and rigour, he subdued the hearts of his high-minded countrymen, and soon superadded to his claims of power the more imposing and indissoluble bonds of superstitious reverence and awe. The capture of Mecca, and the submission of the powerful race of the Koreish, was soon followed by the conversion to Islamism of most of the remoter pagan tribes, until all Arabia bowed the neck beneath his yoke.

Mohammed, having thus become master of all Arabia, made great preparations for the conquest of Syria; but this vast enterprise was reserved for his successors. He gradually, however, paved the way for their successes, and brought the celebrated region of Arabia into one complete and powerful union. He established the law which still obtains in all the Mussulman states, of imposing a personal tax on such subjects as do not embrace Islamism. By this custom, still subsisting among all the sovereigns who acknowledge the Koran, every reputed infidel pays a *kharaaj*, or capitation-tax, over and above the imposts which he supports equally with the rest of the subjects. He absolutely prohibited all idolators from making the pilgrimage to Mecca, or any foreigner from entering the Caaba, under pain of death. These were strokes of profound policy. He retained the pilgrimage to Mecca, which had been of ancient standing among the descendants of Abraham and Ishmael. Though he destroyed the images used at Mecca, as objects of idolatrous worship, he carefully retained the holy relics of the black stone and the supposed impression of Abraham's foot. The black stone had been immemorially venerated there; the angels, it was said, had brought it *white* to the Caaba, and the sins of mankind had transformed it to *black*. Hence, in allusion to this stone, the Orientals use the familiar compliments, '*May God whiten thy face!*' '*May the shah make thy face white!*' &c.

These practices no less forwarded the progress of Islamism than did the sword of Mohammed. Everywhere the petty Arabian tribes overthrew their idols, and submitted themselves to the new faith. Thus was Mohammedanism established, and idolatry rooted out, even in Mohammed's lifetime, throughout all Arabia; and the Arabs, being then united in one faith, and under one prince, found themselves in a condition for making those conquests which extended the Mohammedan faith over so great a part of the world.

In the tenth year of the Hejira (A.D. 631), Mohammed set forth on a solemn and pompous embassy to Mecca, accompanied by all his wives, and by at least 90,000

pilgrims. He sacrificed with his own hands sixty-three victims, and liberated sixty-three slaves, in thanksgiving for each year of his life; he shaved his head, and scattered the hair amongst the multitude, who eagerly seized portions of it, which they treasured as sacred relics. He closed the solemnity with the following apostrophe, which, as if pronounced from heaven, concludes the Koran:—'*Henceforth, wretched and miserable shall they be who deny your religion. Fear not them, but fear me; this day I have perfected your religion, and completed my grace toward you. I have willed that Islamism be your religion.*' He established the lunar movable year, still in use with the Mohammedans; and finally, as supreme Pontiff, or Imam, dismissed the people with a farewell, the last, as he declared, that he should give them; whence this pilgrimage derived its name of the Farewell.

Mohammed, having returned to Medina, now drew near the close of his extraordinary and fortunate career. His health had been for three years on the decline; but he had neither relaxed his duties nor his labours. Being at length affected with a mortal malady, he was conveyed to the house of his favourite wife, Ayesha, where he expired, in the eleventh year of the Hejira (A.D. 632), in the sixty-first year of his age. Of all his wives, the first alone bore him any children, of whom only his daughter Fatima, wife of Ali, survived him.

Having thus presented a sketch of the life of this remarkable man, we proceed to a notice of the religion which he founded. As already mentioned, Mohammed must be viewed chiefly in the light of an improver on the old modes of belief and practice of the Arabians; and his merit (if we may so call it) in this respect appears to have been, the combining of a variety of religious opinions into one form of faith, superadding an implicit belief in his own prophetic character, and enunciating the whole of his code in the writings of the Koran. At the period of his death, he bore the character both of a divinely-appointed vicegerent and of a secular prince, the latter being gained by his conquests; and his successors claimed the same double qualification. After the prophet's decease, the election of a successor occasioned considerable excitement, his father-in-law Abubeker, and his son-in-law and cousin Ali, each claiming the office of caliph. Abubeker was finally successful in the competition, and he, as is known to the readers of history, was succeeded by the ferocious Omar. Ali became the fourth caliph, but he was summarily cut off by poison; and from the long contests which afterwards occurred, it is difficult to say in what line the caliphate was ultimately settled.

The Koran, or prescribed record of the Mohammedan faith, consists of 114 chapters, each with a distinct title, but varying in length from a few sentences to several pages. No continuous subject can be said to run through the work, each chapter being in the form either of a separate revelation, or treating of a peculiar matter in faith, morals, or law. Among the titles to the various chapters we find the following:—The Cow; the Family of Imran; Women; the Spoils; Jonas; Joseph; Abraham; The Night Journey; The Cave; The Assembly; The News; Divorce; The Fig; The Resurrection, &c. The whole is a singular jumble of highly poetical passages, narratives characterised by great simplicity and beauty of style, garbled extracts from the Old Testament, and pious exclamations. The praise of the Almighty is a prevailing theme in all parts of the work, along with a deep inculcation of the principle that Mohammed is the greatest of all prophets who ever appeared on earth. The work certainly contains much that is excellent as respects moral admonition, but also a great deal that is incomprehensible and ludicrous. Mohammed did not live to complete his Koran in the shape we now see it. With the assistance, unquestionably, of a person versant in the Jewish Scriptures, he from time to time, as was suggested by passing circumstances, composed his fragments, which he declared to have been revealed to him from God by the Angel Gabriel; and these having been collected by his

followers, were, by succeeding caliphs, formed into a volume entitled, by way of pre-eminence, *Al Koran* (pronounced *Kooraan*), or The Book.

Whatever we may advance against the authority of the Koran, it is certain that it has been received by Mohammedans with a degree of reverence rarely witnessed among Christians towards the Holy Scriptures. In it they view the whole code of religious belief, civil law, and moral obligation. The belief which they generally profess, as drawn from the Koran, consists in the following leading points:—Religion is divided into two branches—faith and practice. Faith includes belief in God, in his angels, his revelations in the Koran, his prophets, the resurrection and day of judgment, and God's absolute decrees. Practice includes prayer, comprehending under this head the purifications necessary before prayer, alms-giving, fasting, and the pilgrimage to Mecca. The religion, as a whole, is called the religion of *Islam*, or *Islamism*. 'The word *islam*—we quote the *Encyclopædia Americana*—signifies an entire submission to the will of God, and thence the attaining of security, peace, and salvation. This act is performed, and these blessings are obtained, according to the doctrines of the Koran, by acknowledging the unity of God and the apostleship of Mohammed. Every man who makes this profession (*akama*) is a *Moslem*—that is, one who has entirely given himself up to the will of God—and is on that account in a state of salvation (*salam*). As it happens that *Muslimani*, the dual of *Muslim*, is commonly substituted for the singular by the Persians and Turks, the words *Musliman* or *Muslimans*, has in those, as well as in European languages, now nearly superseded the shorter and more correct term.'

The notions of God and his attributes appear from the Koran to be just, and favourable to devotion. The belief in angels is, however, mingled with many singular fancies. They are believed to have been created by fire, to have pure and subtle bodies requiring no support, and that there is no distinction of sexes among them. The angels are supposed to have various forms and offices assigned to them; some adoring God, singing praises to him, or interceding for mankind, while others are engaged in writing down the actions of men, carrying the throne of God, and performing other services. The Mohammedans also believe that there are two guardian angels appointed to attend upon every human being, who observe and write down his actions, and who are changed every day.

There are four angels whom the Mohammedans believe to be more in the favour of God than any of the others. These are Gabriel, who is sometimes called the Holy Spirit and the Angel of Revelations, from his being employed in writing down the decrees of God; Michael, the friend and protector of the Jews; Azrael, the angel of death; and Israfil, who is to sound the trumpet at the resurrection. The devil, called in the Koran *Eblis*, is supposed to have been one of those favoured angels; but he fell, because he refused to worship Adam, with the other angels, at his creation. In the eighteenth chapter of the Koran, however, he is said to have been one of the *genii*, a species of beings whom the Mohammedans believe to be intermediate between angels and devils. The *genii* are said to have been created, like the angels, of fire, free from smoke; but, unlike the angels, they eat and drink, propagate their species, and are subject to death. Some are supposed to be good, and others bad. In the seventy-second chapter of the Koran, a company of the *genii* are described as believing in the doctrine of Mohammed, on hearing him read it.

With respect to the belief in prophets, the Koran inculcates the doctrine that God has at various times given revelations of his will to several prophets, whose books originally amounted to one hundred and four. Of these, ten were given to Adam, fifty to Seth, thirty to Enoch, ten to Abraham, and the other four to Moses, David, Jesus, and Mohammed. All these, except the four last, they believe to be lost; and that, after Mohammed, no other revelation may be expected. It appears that they have some prayers of Moses, Jonas,

and others, a book called the *Psalms*, which consists of extracts from our version mixed up with other matter, and a history of Christ, said to be written by St Barnabas. In this book, Christ is made to predict the coming of Mohammed under the title of 'Famous,' that being the signification of his name in Arabic. According to tradition, there have been from time to time no fewer than 224,000 prophets sent into the world; and of these, 313 were apostles, charged with commissions to reclaim mankind from the infidelity into which they had fallen. Six of them—namely, Adam, Noah, Abraham, Moses, Jesus, and Mohammed—were sent especially to promulgate new laws or dispensations. The Mohammedans believe some of these apostles to have been superior to the others; to the last six, for instance, they give the first place. They believe them to have been free from great sins, although not perfectly pure, and that they all professed the same religion. In this list of prophets they introduce many whose names are mentioned in Scripture as patriarchs, such as Adam, Seth, Lot, &c. and also many others who are not mentioned in the sacred writings. But of all the prophets of God, the Koran enforces the leading doctrine that Mohammed is the greatest, and that his mission is to be believed in, under the most severe penalties. 'God will render of non effect the works of those who believe not, and who turn away men from the way of God; but as to those who believe and work righteousness, and believe in the revelation which hath been sent down unto Mohammed (for it is the truth from their Lord), he will expiate their evil deeds from them, and will dispose their heart aright. When ye encounter the unbelievers, strike off their heads, until ye have made a great slaughter among them; and bind them in bonds: and either give them a free dismissal afterwards, or exact a ransom, until the warriors shall have laid down their arms. This shall ye do.'—Chap. xlvii. From numerous passages of this kind, the Mohammedans have framed the well-known brief enunciation of their belief—'There is no God but God, and Mohammed is his prophet,' a saying which is ever in their mouths, and may be called their popular creed.

Regarding the resurrection, the Mohammedans believe that, when a dead person is laid in the grave, he is received by an angel, who gives him notice of the coming of the two *Examiners*. These are two black angels, of a terrible appearance, named *Mouker* and *Nakir*. They order the dead person to sit upright, and examine him concerning his faith in the unity of God and the mission of Mohammed. If he answer correctly, his body is allowed to lie at rest, and is refreshed with the air of paradise; but if he appear sceptical, they beat him on the temples with iron rods, till he cries with anguish so loud as to be heard by all except men and *genii*. As to where the soul dwells after death, the Mohammedans seem to have a variety of opinions, which need not be particularised. Mohammedans are also divided as to the nature of the resurrection, some believing that it will be merely spiritual, others that the body only will be raised; but it is believed that all who have ever lived will appear for judgment. It is likewise believed that the irrational animals will be judged at the resurrection, and weak animals will take vengeance on the strong until satisfaction is given to the injured. The Koran enjoins kindness to all animals whatsoever, although it pronounces some to be unclean; and it is allowed that the conduct of Mohammedans in this respect far exceeds that of the generality of Christians.

It is supposed by the more orthodox Mohammedans, that the books wherein the bad actions of a man are registered will be put into one scale, and the good into another, and according as these preponderate, sentence will be given. After this will follow the satisfaction which every one takes of his fellow, or the retaliation made by them for the injuries they have received. The manner of giving this satisfaction will be to take away from one man a portion of his good works, and give it to one whom he has injured. 'Which being done,' says Mr Sale, 'if the angels say, Lord, we have given

to every one his due, and there remaineth of this person's good works so much as equalleth the weight of an ant, God will of his mercy cause it to be doubled to him, that he may be admitted into paradise. If, on the contrary, his good works be exhausted, and there still be some to receive satisfaction from him, God will order an equal amount of their sins to be heaped upon him, that he may be punished in their stead. The trials being over, and the assembly dissolved, the Mohammedans hold that those who are to be admitted into paradise will take the right-hand way, and those who are destined for hell-fire the left; but both of them must first pass the bridge called in Arabic *al Sirat*, which they say is laid over the midst of hell, and describe to be finer than a hair, and sharper than the edge of a sword.

The Mohammedans believe hell to be divided into seven apartments, designed for the reception of different degrees of sinners. The first is destined to receive the wicked Mohammedans, the second for the Jews, the third for the Christians, and the rest for other sects and unbelievers. Over these will be placed nineteen angels, to whom the condemned will confess the justness of God's sentence, and beg them to intercede with him in their behalf. The punishment of infidels will be continued for ever, but wicked Mohammedans will be released after a certain period of suffering.

Before entering paradise, the righteous will drink at the pond of Mohammed, which is supplied with water from the rivers of paradise. It is described as a month's journey in compass, and whoever drinks of the water will thirst no more. It is a matter of keen dispute whether paradise is already created, many supposing that it will be different from the paradise in which Adam was placed. The more orthodox opinion, however, is, that it is the same, and that it was created before the world. It is supposed to be situated above the seven heavens, immediately under the throne of God, and is described as a place of surpassing beauty. The trunks of the trees are of gold, one of which, the tree of happiness, will yield all sorts of fruit for the consumption of true believers.

God's absolute decree and predestination of both good and evil, is a doctrine which Mohammed always took occasion to impress upon his followers. He said that God had not only predetermined the adverse or prosperous fortune of every person in the world, but also his faith or infidelity, which fate it is impossible by any foresight to avoid. By this doctrine, Mohammed taught his followers to have the greatest contempt for danger and suffering, which feeling was of material service to him in the propagation of his creed.

Of the four points of religious practice required by the Koran, prayer is the first. Mohammed included under this act purifications of the body, by total immersion at certain periods, and by washing the face, hands, and feet, at others. To make his followers punctual in the observance of these purifications, Mohammed declared that the practice of religion is founded on cleanliness, without which prayer would not be heard by God. A Mohammedan is obliged to pray five times in the twenty-four hours, at stated periods—before sunrise in the morning, when noon is past, in the afternoon before sunset, in the evening after sunset, and before the first watch of the night. Public notice is given of these periods by the *muezzins*, or criers, and every Mohammedan prepares himself for prayer. This he performs either in the mosque, or any other place, providing it be clean, after a prescribed form, and with a certain number of ejaculations, which he is on no occasion to abridge, unless when on a journey or preparing for battle. It is also necessary that he should kneel in a humble posture, and turn his face towards Mecca, as expressed in the second chapter of the Koran: 'Turn, therefore, thy face towards the holy temple of Mecca, and wherever ye be, turn your faces towards that place.' The direction of Mecca is pointed out within the mosque by a niche on the outside, by the situation of the doors and the steeple; and tables have

been calculated for finding this out when they have no other guide. A Mohammedan is also obliged to lay off all costly parts of his dress before prayers, that he may not appear proud. Females are not allowed to enter the mosques along with the men, but they may visit them at other periods.

The prayers of the Mohammedans consist chiefly of pious exclamations, praising the greatness and goodness of God; and one of the more common of these prayers consists in a repetition of the first chapter of the Koran, called the *Fathat*, or Belief. It is in these words: 'Praise be to God, the Lord of all creatures; the most merciful, the King of the Day of Judgment. Thee do we worship, and of Thee do we beg assistance. Direct us in the right way, in the way of those to whom Thou hast been gracious; not of those against whom Thou art incensed, nor of those who go astray.'

Alms-giving is a necessary part of the religious practice of Mohammedans. These consist of cattle, money, corn, fruits, and wares which can be sold. At the end of the fast of the Ramadan, every Mohammedan is obliged to give in alms, for himself and for every one of his family, a measure of wheat, barley, dates, raisins, rice, or other provisions. 'The legal alms,' says Mr Sale, 'were at first collected by Mohammed himself, who employed them as he thought fit in the relief of his poor relations and followers, but chiefly applied them to the maintenance of those who served in his wars, and fought, as he termed it, in the way of God. His successors continued to do the same, till, in process of time, other taxes and tributes being imposed for the support of the government, they seem to have been weary of acting as almoners to their subjects, and to have left the payment of them to their consciences.'

Fasting is the third point of religious practice amongst the Mohammedans. It consists in abstaining from satisfying the appetites; in restraining the ears, eyes, tongue, hands, feet, and other members, from sin, and the fasting of the heart from worldly cares, and thinking of nothing but God. During the month of the Ramadan, Mohammedans are obliged to fast from the time the new moon first appears till the appearance of the next new moon. In this month they abstain from eating and drinking from daybreak till sunset; and this injunction they observe so strictly, that while they fast, they suffer nothing to enter their mouths or the other parts of the body, esteeming the fast broken if they smell perfumes, bathe, or even purposely swallow their spittle. The old and the sick are exempted from this fast; but in the case of the latter, when they recover, they must fast the allotted number of days. After sunset the people are allowed to refresh themselves—to eat, drink, and enjoy the company of their wives till daybreak. The more scrupulously devout, however, commence the fast again at midnight.

According to the injunctions of the Koran, every man is to perform a pilgrimage to Mecca once in his life, except prevented by poverty or ill health. It is clear that such an observance is altogether inapplicable to the condition and situation of the great bulk of the human race; and what is impossible in human practice, can never have been enjoined by the Creator. Mohammed, it is evident, only thought of Arabia and its neighbourhood, when he planned this idle ceremonial observance. Aware that, even within that limited district, his followers would have a difficulty in performing such a pilgrimage, he allows any one who is wealthy enough, to hire and send a deputy; many, we are informed, neglect this duty who cannot plead a lawful excuse. The temple of Mecca stands in the midst of the city, and is called the sacred or inviolable temple. Within it are said to be the tomb of Ishmael, and a remarkable black stone, which bears the mark of Abraham's foot. This temple was held in great veneration by the Arabians long before the time of Mohammed; some even say that it was built by Adam immediately after his expulsion from paradise. To this place pilgrimages are made from all parts where the Mohammedan religion is professed. A number having collected from any par-

## PAGAN AND MOHAMMEDAN RELIGIONS.

ticular district, form themselves into a caravan for the purpose of mutual protection, which is very necessary from the number of bandit tribes who infest the route. The pilgrims meet at different places around Mecca, according to the direction in which they have come, and are obliged to be there by the beginning of the first month, called Dhulhaji.

'It is not,' says Mr Lane, 'by the visit to Mecca, and the performance of the ceremonies of circuiting the temple seven times, and kissing the black stone in each round, and other rites in the holy city, that the Moslem acquires the title of the *hadji* (pilgrim). The final object of the pilgrimage is Mount Arafat, six hours' journey from Mecca. During his performance of the required ceremonies at Mecca, and also during his sojourn at Arafat, and until his completion of the pilgrimage, the Moslem wears a peculiar dress called *ahram*, generally consisting of two simple pieces of cotton, or linen, or woollen cloth, without seam or ornament, one of which is wrapped round the loins, and the other over the shoulders; the instep and heel of each foot, and the head, must be bare; but umbrellas are now used by many of the pilgrims. It is necessary that the pilgrim should be present on the occasion of a *Khooteb*, which is recited on Mount Arafat in the afternoon of the 9th of the month Dhulhaji. In the ensuing evening, after sunset, the pilgrims commence their return to Mecca. Halting the following day in the valley of Mina, or Moona, they complete the ceremonies of the pilgrimage by a sacrifice (of one or more male sheep, he-goats, cows, or she-camels, part of the flesh of which they eat, and part give to the poor), and by shaving the head and clipping the nails. Every one after this resumes his dress, or puts on a new one, if provided with such. The sacrifice is called *el fida* (or the ransom), as it is performed in commemoration of the ransom of Iahmael by the sacrifice of the ram, when he was himself about to have been offered up by his father; for it is the general opinion of Mohammedans, that it was this son, and not Isaac, who was to have been sacrificed by Abraham.

The laws by which Mohammedans are governed are in a great measure derived from the Koran. Where this sacred book is silent, reference is made to the traditions of the prophet to direct the decisions of the judge. Regarding the Koran as a book of jurisprudence, we quote the following from the Library of Useful Knowledge:—'Nothing but the prejudices of education could make a reasonable man look upon the Koran as a book of jurisprudence capable of conveying instruction to any but a nation of savages. Deficient in form, deficient in clearness, incomplete, it possesses not one single quality requisite to a body of law. In the midst of a vast farrago of nonsense, hidden amidst unmeaning explanations and dark mysterious prophecies, there sometimes appears a command respecting the distribution of property or the punishment of offenders. But no explanations are given—no regular description of the means by which property may be acquired; no enumeration of those by which the rights to it may be lost, is even attempted. The rights of individuals, in their several capacities, to the services of others, are nowhere distinctly mentioned; nor is there the most distant approximation to any systematic view of the several obligations to which it was intended to subject the members of the community. As occasion prompted, or when a dispute happened, Mohammed was accustomed to issue a revelation, which answered for the immediate purpose. But the original unwritten customs of the Arabs remained in full force, receiving little modification from the decrees of the prophet. One advantage, and one alone, he may be supposed to have originated—his were *written* decrees; it was a commencement for a body of laws, though a rude and imperfect one. This benefit, however, is more than counterbalanced by the evil of their being irrevocable. What the ignorant barbarian instituted, succeeding generations have been obliged to retain. No matter how absurd, how injurious to the decree, religion commands the faithful Moslem to abide

by it. The Almighty was its author, and he is all-wise; and moreover is as wise at one time as another. How, then, shall we pretend to amend the divine ordination, or fancy that he himself need amend it? The conclusion is irresistible, provided the premises be allowed. The nations who have assumed the Moslem faith have consequently remained, and while they continue to profess it must remain, barbarians.'

One of the worst features of the Mohammedan faith is the degraded position which it assigns to women. This indeed forms a radical error in the constitution of society in Mohammedan countries, and must be removed before there can be a steady advance in rational improvement. Women are considered in every respect inferior to men. Few of them, even among the highest classes, receive any instruction; they are carefully secluded from public observation; assigned in marriage without their own consent, on payment of a trifling sum in form of dowry; and are divorced at pleasure—all which tends to debase their minds, and to produce the worst kind of social vices. Polygamy and legal concubinage add to the evils caused by such practices. The Koran allows a man to marry four wives, and to maintain as many concubine slaves as he may choose. He may divorce any of his wives at any instant which caprice or passion may suggest, merely by uttering the emphatic words, 'Thou art divorced!' and she must return to her parents or friends accordingly. He may take her again as a wife, and again divorce her; and even divorce her a third time, provided she has in the interval been married to and divorced from another man. Mr Lane, in his work on Egypt, says, that he has known cases in which men have, in the course of a few years, married as many as twenty or thirty wives; and also cases of women who had been married to a dozen or more men successively. In most instances, we are told, a man marries no more than one wife; but as these practices are common, we can easily judge of the depravity of manners which prevails in those countries professing the Mohammedan creed.

From the manner in which females are treated, it has been generally supposed by Christians that the Mohammedans believe that women have no souls. But this is a mistake. Women are believed to have souls, and are not to be excluded from paradise, though they are there to perform offices of a subservient nature. The meanest person in paradise, it is believed, 'is to have eighty thousand servants, and seventy-two wives of the girls of paradise, besides the wives he had in this world; that he is to inhabit a tent composed of pearls, iacinths, and emeralds; at meals he will be served in dishes of gold; and he is to be at liberty to drink freely of the wine of paradise, which will not intoxicate.' In such promises of felicity, we have a striking proof of the mean ideas of eternal happiness formed by the prophet, as well as of his knowledge of mankind.

The Koran forbids the use of wine or any intoxicating liquors; and this is among the best injunctions which it contains. Opium and other inebriating drugs are understood to fall within the line of prohibition, though not mentioned. The use, therefore, of either intoxicating drinks or drugs, is considered immoral in all Mohammedan countries. Mussulmans of all ranks are remarkable for their sobriety and temperance in food. The eating of swine's flesh is strictly prohibited; and indeed most animals forbidden to be eaten by the Mosaic law, are alike forbidden by that of Mohammed. All animals used for food must be killed by cutting their throat; and, in performing the operation, the butcher must say, 'In the name of God! God is most great!' Gambling is also prohibited; also usury, and the making of any images or pictorial resemblances of anything that has life. Perhaps the desire to extinguish idolatry influenced the prophet in laying down the last-mentioned law. Apostacy from Islamism is deemed a most heinous sin, and must be punished with death.

The Mohammedan creed enjoins no sabbath, like that of either the Jews or Christians, but selects Friday as a day in the week to be distinguished by more than

## CHAMBERS'S INFORMATION FOR THE PEOPLE.

usual solemnity of devotion. Friday has been pitched upon, because it is said Adam was created on that day, and because the resurrection is prophesied to be on that day of the week. Perhaps a desire to avoid Saturday or Sunday, the days revered respectively by Jews and Christians, may also have influenced its adoption. Friday is called *El-Goomah*, or 'The Assembly'; and on the forenoon of that day large congregations assemble in the mosques, when, in addition to the usual prayers, a sermon or address is delivered, and lessons read from the Koran, by the officiating imâms. After this service, all kinds of work go on as usual.

All religions, above the meanest paganism, have possessed a body of priests or functionaries, to whom the knowledge of the faith was confided, and by whom its precepts were enforced. Considering that Mohammed must have been conversant with the constitution and import of the Jewish priesthood, as laid down in the Levitical law, and also acquainted with the arrangements of the Christian church, it is remarkable that he instituted no order of clergy, but, on the contrary, left his religion to be professed by the people at large, without any distinction as to rank or qualification. On this account Mohammedanism has no priesthood, and cannot be said to constitute in any country what we understand by the term church. Wherever it is established as the religion of the community, *mosques* or chapels have been erected, generally by endowments from wealthy individuals; and these are individually under the charge of a warden, who is custodian of the revenues, and appoints the ministers of religion and inferior servants. 'Two imâms,' says Mr Lane, 'are employed to officiate in each of the larger mosques: one of them, called the *khateeb*, preaches and prays before the congregation on the Friday; the other is an *imâm rutibî*, or ordinary imâm, who recites the five prayers of every day in the mosque, at the head of those persons who may be there at the exact times of those prayers: but in most of the smaller mosques both these offices are performed by one imâm. There are also to each mosque one or more *muessims* (to chant the call to prayer), and *doorwabs* (or doorkeepers); and several other servants are employed to sweep the mosque, spread the mats, light the lamps, and attend the water-wheel by which the tank or fountain, and other receptacles for water, necessary to the performance of ablutions, are supplied. The imâms, and those persons who perform the lower offices, are all paid from the funds of the mosque, and not by any contributions exacted from the people. The condition of the imâms is very different, in most respects, from that of Christian priests. They have no authority above other persons, and do not enjoy any respect but what their reputed piety and learning may obtain them: nor are they a distinct order of men set apart for religious offices, like our clergy, and composing an indissoluble fraternity; for a man who has acted as imâm to a mosque, may be displaced by the warden of that mosque, and, with his employment and salary, loses the title of imâm, and has no better chance of being again chosen for a religious minister than any other person competent to perform the office. The imâms obtain their livelihood chiefly by other means than the service of the mosque, as their salaries are very small, that of a *khateeb* being generally about a piasre (nearly 2½d. of our money) per month.'

'The Mohammedans,' continues the same authority, 'observe the utmost decorum in their public worship. Their looks and behaviour in the mosque are not those of enthusiastic devotion, but of calm and modest piety. Never are they guilty of a designedly irregular word or action during their prayers. The pride and fanaticism which they exhibit in common life, in intercourse with persons of their own or of a different faith, seem to be dropped on their entering the mosque, and they appear for the time wholly absorbed in the adoration of their Creator.'

Mohammedans have an extreme reverence for a green colour, which is used exclusively as the hue of turbans or other garments by those who claim hereditary de-

scend from the family of the prophet. Europeans generally imagine the crescent to be a common symbol of Mohammedanism, as the cross is of Christianity; but we believe this is founded on mistake. The crescent, from a very early period, was a heraldic ensign of Byzantium or Constantinople, and has been appropriated by the Turks since their capture of that city.

The Mohammedans are generally affected with the most superstitious reverence for imaginary saints and 'favourites of God.' They imagine that idiots and lunatics are under the immediate inspiration of Heaven; and, unless these be dangerously mischievous, they are permitted all sorts of license. 'Most of the reputed saints of Egypt,' says Mr Lane, 'are either lunatics, idiots, or impostors.' Any one who is deranged by religious excitement becomes a *walee*, or an especial favourite of the Almighty, and is supposed to be gifted with supernatural powers. Almost every celebrated saint, deceased, is honoured by an anniversary birthday festival; and on occasion of these festivals, many persons visit the tomb of the saint, both as a duty and as a supposed means of obtaining a special blessing. Besides the various classes of saints, there are different orders of *durweeshes*, or dervises, some of whom subsist by begging, and others by performing at religious festivals; a few devote themselves to religious seclusion, and gain a character for exalted piety.

Mohammedanism, from shortly after the death of its founder, has been divided into two great parties or sects, who split upon the disputes concerning the Caliphate, or spiritual and civil supremacy, and received the name of *Sunnites* and *Shiites*. The Sunnites take their appellation from the *Sunna*, or collections of traditions relating to Islamism, which they believe to be of equal importance with the Koran. The term *Shiites* signifies heretics, which they are called by the opposite party, from their misbelief. The adherents of the doctrine that Ali, son-in-law of Mohammed, was properly his successor, reject the Sunna. The Turks are Sunnites, and the Persians are Shiites, and each hates the other with implacable animosity. The Sunnites, we believe, are reckoned the orthodox sect, and acknowledge the reigning sultan as the true successor of Mohammed.

Besides differing as to the credibility of the Sunna, and the successorship of the prophet, the Mohammedan world is divided into four minor sects—the *Hanafees*, *Shafees*, *Malikees*, and *Hambotees*, being so called from the respective doctors whose tenets they have adopted. 'The Turks,' says Mr Lane, 'are of the first sect, which is the most reasonable.' About the middle of last century, a great schism, or attempt at reformation, broke out in Arabia, headed by Mohammed, son of Abdel Wahab, a pious and learned sheikh. Young Mohammed claimed divine inspiration, and taught, like the Koran (the doctrines of which he but partially received), the existence of an only God, the Creator of the world, the rewarder of the good, and the punisher of the bad; but he rejected all the stories contained in the Koran, especially those concerning Mohammed, whom he considered merely a man beloved of God, but branded the worship of him as a crime directly opposed to the true adoration of the Deity. He also condemned the ornaments and splendour which are found in the mosques and the sepulchres of pretended saints. In short, he stripped Mohammedanism of all its trappings, and reduced it to little else than a pure Theism. All who should oppose this new doctrine were to be destroyed by fire and sword. His doctrines being adopted by some influential chiefs, spread with wonderful celerity, and the *Wahabees*, as his followers were called, shook the stability of the empire of the Turks in Asia. After a hot war of many years, the Wahabees were suppressed by Mehemet Ali, the late pasha of Egypt; but their doctrines are still far from being exterminated.

Of many of the extravagant superstitions connected or disconnected with religious belief, and which have prevailed both in ancient and modern times, a notice will be found in the following number.

## SUPERSTITIONS.

MANKIND have in all ages been prone to the most lamentable superstitions. The enlightened nations of antiquity were no more exempted from them than the most ignorant. The Jews, as we are repeatedly informed in Scripture, could with difficulty be restrained from idolatrous and superstitious practices, and confined to the worship and service of the only true God. This remarkable tendency of the Hebrew nation was in all likelihood caused by their sojourn for the space of four hundred years among the Egyptians, whose whole system of religion was a mass of idolatrous observances. They had a number of ideal gods, to whom they erected temples of prodigious size and architectural splendour; the principal of these deities were Osiris and Isis, which are thought to have been typical of the sun and moon. But they also offered worship to various animals, as the ox or bull (hence the golden calf of the Hebrews), to which they gave the name of Apis; the dog, the wolf, the hawk, the ibis or stork, the cat, and other creatures; they likewise paid adoration to the Nile, personifying it in the crocodile, to which temples were erected, and priests set apart for its service. The Egyptians, notwithstanding their learning (See HISTORY OF ANCIENT NATIONS), also believed in dreams, lucky and unlucky days, omens, charms, and magic. In a word, they were grossly superstitious, and seem to have had but a feeble conception, if any, of the laws which regulate the ordinary phenomena of nature.

The Greeks and Romans possessed an equally insufficient idea of an omnipresent and omnipotent God, the creator and ruler of the universe. Their notions of divinity, like those of other Pagans, were grovelling and contemptible. The gods whom they adored were imagined to have been at one period rulers or heroes on earth, and still had their habitation somewhere within the Grecian territory, or at no great distance from it. Besides their belief in this vain mythology, both Greeks and Romans put faith in divination, oracles, the magical power of amulets, and dreams. Bees, ants, and various reptiles and beasts, were imagined to have the power of giving omens of good or bad fortune. The phenomena of the atmosphere and planetary bodies were likewise a fertile source of superstitious delusions; and so also were certain signs or marks on the intestines of victims slain as sacrifices at the altars. The mode of sacrificing in Greece is worthy of observation. Bulls, goats, sheep, pigeons, cocks, and other creatures, were immolated to the gods of the country. Sometimes there was a hecatomb, or sacrifice of a hundred animals at a time, to appease the manes or restless spirits of the deceased. A notion prevailed that the animals to be sacrificed would show signs of satisfaction on being brought to the altars, if the gods to whom they were offered felt pleased with the oblation. On bringing forward a bull or goat, the officiating priest drew a knife from the forehead to the tail, at which, if the victim struggled, it was rejected, as not acceptable to the gods; but if it stood quietly at the altar, then they thought the gods were pleased with it: yet a bare non-resistance was not thought sufficient, unless it gave its assent by a gracious nod. To try if it would nod, they poured water or barley into its ear. Being satisfied with the sign, the priest proceeded to pour wine, and sometimes fruits and frankincense, between the horns of the victim, and afterwards struck it down, and bled it to death. Great dexterity was requisite in striking down and bleeding a victim; for if it did not fall at once upon the ground, or stamped, or kicked, or struggled to be loose, or did not bleed freely, or seemed to die with pain, it was thought unacceptable to the gods; all these being unlucky omens. To the celestial gods, sacrifices were made in the morning about sunrise; but to the deities

of the lower regions, who were supposed to hate the light of day, they were made at midnight. It was customary on some occasions to dance round the altars whilst they sang the sacred hymns, which consisted of three stanzas or parts. The pouring out of libations of wine to the gods, and a thousand other follies, were perpetrated and believed. The appearance of comets and eclipses were ominous of great public disasters, it being the general belief that they were special signs made to warn mankind of approaching troubles; in all which we see a lamentable proof of the follies and weakness to which even a refined people may be exposed if ignorant of the laws of nature.

The superstitious delusions of the Greeks and Romans may be said to have died out at the final dismemberment of the Roman empire, and the overrunning of western Europe by the Gothic nations. The introduction of Christianity also tended powerfully to root out the old superstitious usages, though a few survived to a later date. For these reasons, the superstitions and matters of credulous belief which afterwards affected the people of northern and western Europe, including the British islands, were in a great measure of Scandinavian and Gothic origin.

### SCANDINAVIAN SUPERSTITIONS.

The superstitions of the European Northmen, or Scandinavians—under which term are included the early inhabitants of Denmark, Norway, Sweden, and Iceland—were of a kind remarkably accordant with the cold and stern character of the regions which they occupied. Like the ancient Greeks, the Scandinavians had seats of the gods and of the blest, which they called Asgard and Valhalla (or Valhalla), and these bore the same relation in their character to the Olympus and Elysium of the Greeks, that the countries of the north, with their stormy climes, their icy mountains, and perilous waters, bore to the perfumed and verdant plains of Hellas, and the fair blue skies overhanging the smooth Ionian Sea. Nothing could afford better proof of the utterly fanciful nature of all these mythologies, than the fact, that they were thus modelled and modified in every case by the earthly habits, the wants and likings, the territorial position, and ignorance of geography and astronomy, of the individual tribes among whom they respectively originated.

The deification of one or more great princes or rulers seems to have constituted the basis of the Scandinavian, as well as of every other Pagan mythology. Odin, the supreme deity of the Scandinavians, and the ruler of heaven and earth, appears, like the Hellenic Jupiter, to have been a distinguished chief and warrior of early times. Although it is asserted by some that a divinity of the name of Odin was worshipped from the most remote ages, there is reason to believe that the worship of this personage, in the north at least, had its real origin a few centuries before the commencement of the Christian era, when a powerful chieftain of the name was driven by the Romans from his dominions between the Euxine and Caspian, and took refuge in Scandinavia, the whole of which he subjected to his sway. Like Mohammed, this chief appears to have established a new religion, of which he himself assumed to be the earthly head, as the servant or minister of a divine being of the same name. In the course of time, however, this distinction was entirely lost, and the persons and acts of the divine and earthly Odin became inextricably blended in the mythology and traditions of the north. The great records of the religious and legendary knowledge of the Scandinavians are the Eddas and Sagas of Iceland, partly written in poetry and partly in prose. The oldest of the Eddas, a series of poetical fragments, was col-

lected from oral tradition in the eleventh century, and the others are of later date. The acts of the deities and heroes of the north, their loves and wars, the creation of the world, and prophetic revelations, form the general subject of these pieces.

The Scandinavians, like the Greeks, believed that the universe was originally a chaos, or mass of confused vapours; peopled by a race of Rimthursar, or evil spirits of gigantic bulk. A being of nobler nature sprang up among these, named Bure, from whom were descended Odin and his two brothers Vile and Ve. These younger divinities followed exactly the same course with the northern giants that was pursued by Jupiter and his brothers with regard to the Titans, or older and gigantic deities of Greece. Odin began to war with the Rimthursar, and having at last overcome their great chief Ymer, he created the world out of that giant's body. His flesh became the mould, his bones the rocks, his hair the vegetable tribes, his blood the ocean, and his skull the heavens, at the four corners of which were placed certain dwarfs, called North, South, East, and West, whose duty it was to sustain the celestial dome. After this, the luminaries of the sky were set in their places, and the order of the seasons appointed. Natt (Night) wedded one of the Aser, or celestial family of Odin, and gave birth to Dag (Day). These deities travel alternately round the world in cars, drawn by single horses. Every great body, as in the Grecian mythology, was represented by a divinity. Frigga, or the Earth, was the daughter of Odin, and also became his wife. The inhabitants of the earth, or mankind, were created by Odin and his brothers. Two pieces of wood, the one of ash and the other of elm, formed the materials of the first pair of mortals, who were distinguished for personal beauty and intellectual ability.

The race of deities inhabited Asgard, a place supposed by some to have been the city in Asia whence the real or mortal Odin was expatriated. The fabulous Asgard was pictured as containing numerous palaces and halls, the largest of which was the Mansion of Joy, where Allfader (Odin) sat on his throne amid his divine family. This throne was named Lid-skialfa, or the Terror of Nations, and from it he could overlook the whole earth. Two ravens, Hugin (Spirit) and Muninn (Memory), sat always at his ear, and communicated to him intelligence of all things that were going on in the universe. Among the deities who dwell in Asgard, one of the most important was Thor, or Asathor, son of Odin by Frigga, and the Mars, or warrior-god, of the Scandinavians.

Thor is described as the god of thunder, and the strongest of beings, earthly or heavenly. He is the son of Odin and Frigga, or, in other words, of the Sun and the Earth. When he moves, the earth trembles. He holds in his hand a powerful hammer called the Crusher (*mölner*), with which he annihilates all who oppose him, and who offend the gods. In battle, Thor is always girt with a magic girdle, which has the power of inspiring him with a divine fury, and redoubling his strength. On his right hand he wears an iron gauntlet, with which he grasps and wields the formidable crusher. This latter instrument was forged by a dwarf named Sindri, the prototype of the deformed blacksmith-deities of the Greeks, Vulcan and his Cyclops. The hammer possesses the wonderful power of never missing its aim, and when launched at any object, returns to the hand of Thor, after having destroyed his foe. Thor is sometimes called Aukistor, or Thor of the Car, from his riding on a chariot, drawn by two powerful he-goats, named Sangniost and Tangrisner. This deity has a spouse named Sippa, famous for her beautiful hair.

After Odin, Thor was the most cherished deity of Scandinavia, and had statues and temples erected to him everywhere. The statues of him were usually formed of clay, and represented a tall figure, with a red-painted beard, indicative of the lightning which he was supposed to wield. Bread and meat were supplied daily to the god by his worshippers, and at stated times libations were poured out in his honour.

Balder, the second son of Odin, was the most beautiful and amiable of the Aser, or gods. Unlike the rest of his brethren, he was fond of peace, and had the power of allaying tempests, and acting as a mediator, to avert divine wrath. His decrees were irrevocable. In some points he resembled the Apollo of the Greeks, but the general qualities of that personage found a closer representative in Braga or Bragi, the god of eloquence and poetry. Niord, the god of the sea, and his son Freys, the god of rain, were also important deities of the north. Every element, or important natural phenomenon, was under the guidance, in like manner, of some celestial personage. Frigga, the Scandinavian Juno, was the bestower of fertility and plenty. Freia, or Freys, the daughter of Niord, was the Venus of Asgard and the patroness of matrimony. Freia was assisted in her duties by Siona and Sofna, the first of whom made lovers faithful, while the other reconciled them when they quarrelled. Eyra was the physician of the gods. There were various other minor divinities in the Scandinavian mythology, though not nearly so many as in the Grecian roll. The deficiency was made up among the northern by the assignment of more multitudinous duties to the greater deities. Thus Odin, from the extent of his government, received as many as one hundred and twenty distinct names, each indicating some individual quality ascribed to him.

The great hall appointed for the reception of the spirits of the brave, when they left earth for the seat of the gods, was called Valhalla. Twelve beautiful, yet terrible nymphs, named Valkyries (*choosers of the slain*), were the guides of the good spirits to the hall of Valhalla, and supplied them with mead. The occupation of drinking this northern nectar, and of eating the fat of the wild boar Serimmer—which, after serving as the daily food of thousands, became whole again every night—filled up all those intervals of time in Valhalla that were not passed in fighting. None but those who had shown surpassing bravery on earth were admitted into this Scandinavian paradise; and when there, their daily amusement was to fight with one another till all, or nearly all, were cut in pieces. But little harm was done in this way, for the spiritual bodies soon reunited, and enabled the warriors to appear, entire in lithé and limb, at the feasts that followed these extraordinary engagements. The skulls of enemies were the drinking-cups used at the entertainments of Valhalla, and the guests are described as being almost perpetually in a state of inebriation. It was only when the cock announced the arrival of morning that these terrible heroes arose from table, to issue to the field of battle through the five hundred and forty gates of Valhalla, and hack each other to pieces anew. Such was the never-ending round of employment destined for the departed heroes of Scandinavia.

The mythology of the Scandinavians survived till a much later date than any other system of heathen worship in Europe. It was not abolished till the eleventh century. St Olaf, king of Norway, and a zealous supporter of Christianity, usually receives the credit of having overturned this most barbarous form of religion. In the course of his efforts to christianise his subjects, he ordered a statue of Thor, and the pedestal on which it stood, to be broken in pieces, and showed the people that the meat which had been laid down for the use of the god was not eaten by him, but by a host of rats and other vermin that had formed a lodgment about the foundation of the colossal image. Whatever might have been the influence of the mythology of the Scandinavians in Britain, it disappeared shortly after its overthrow on the continent of Europe, or only lingered in a kind of traditional existence amidst the remote islands of Orkney and Shetland, till finally banished by the progress of a more general intelligence. The dread names of Odin, Thor, and other deities of the north, who for centuries weighed down the human faculties, and kept up the reign of superstition, are now only perpetuated in the appellations affixed to some of the days of the week. Thus

our term *Wednesday* is derived from Odin's or Wodin's day, that being the day of the week in which the northern Jupiter, or supreme ruler of the gods, was most honoured and worshipped. *Thursday* is from Thor, the second in dignity among these fabulous deities: as this day was called *Dies Jovis* by the Romans, we have here a confirmation that Thor the thunderer was equivalent either to Mars, or the thundering Jove of the Grecian mythology. *Friday* takes its appellation from Freya, the daughter of Niord, and corresponds with the *Dies Veneris*, or Venus day of the Greeks and Romans. *Saturday* is derived in the same manner from the god Sæter of the Scandinavians, and Saturn of the Greeks. *Tuesday*, or anciently *Tiesday* (a pronunciation still preserved in Scotland), is supposed to be from Tisa, the wife of Thor, and the reputed goddess of justice. *Sunday* and *Monday* were respectively named from the Sun and Moon, both by the northern and southern nations of Europe, from a remote period of time. The circumstance of there being such a marked resemblance between the characters of the deities whose names were employed to distinguish the same days of the week both by Greeks and Scandinavians, is not a little remarkable, and has never, as far as we know, been the subject of explanation by philologists or antiquaries. The fact is only certain, that the names of the days of the week now used by every civilised people, are founded upon the mythological observances of either the Grecian or the Scandinavian races.

#### ANGLO-SAXON SUPERSTITIONS.

At a comparatively early era, the mythology and minor superstitions of the Scandinavians, as well as the follies of Druidism, disappeared in Britain as the familiar superstitions of the Anglo-Saxon race became predominant. Like the Scandinavians of the north, the Anglo-Saxons deduced their descent from Odin, whom they worshipped along with Thor, Freya, and other imaginary deities of the Gothic people. They also worshipped idols emblematic of the sun, moon, earth, and various seasons and circumstances. In particular, they sacrificed to one goddess called Eostre, in the month of April, and her name still expresses the festival of *Easter* in the Christian church. In token of devotional feelings towards the sun, they solemnised a festival to that luminary on the day of December in which the days began to lengthen, a log of wood being burnt on the occasion, as an emblem of returning light and heat. From this ancient practice, therefore, may be traced the custom of burning the Yule log at Christmas, which is still continued in many parts of England. Among the Anglo-Saxon superstitions was included a belief in giants, dwarfs, and elves, all of a spiritual order, but partaking in some degree of human attributes and feelings. In the term *elf* or *elven*, we have one of the earliest traces on record of those ideal fairy tribes who afterwards figured in the familiar superstitions of the British islands. The Gothic nations, of whom the Anglo-Saxons were a branch, had various orders of elves, who were understood to haunt the fields, the woods, mountains, and waters, and received denominations accordingly, as field-elfin, dun-elfin, &c. Whether this varied race of spirits originated in the East, whence so many superstitions spread into ancient Europe, is not satisfactorily known, although it is probable that they did, and were of the same genus as the *peri* of the Persians, a being not dissimilar in character to our fay or fairy. Both in the Scandinavian and Anglo-Saxon superstitions, elves formed an important order of beings, not unlike in character to the demigods, naiads, dryads, and other imaginary spirits of the Greek and Roman mythologies, and, like them, exerted a certain influence over human affairs.

Besides a belief in these mysterious elfin tribes, the Anglo-Saxons brought with them to England the still darker and more dangerous doctrines of witchcraft and divination, before which the reasoning powers of the people quailed, and all intellectual advancement was

impeded. The general introduction of Christianity about the year 600, abolished, as a matter of course, the grosser Pagan observances, but failed to extirpate the more familiar and less obvious superstitions of the people. Witchcraft, wizardry, magic, divination, preparations of charms, and other mystic follies having no foundation in truth, continued to flourish, although opposed both by the more intelligent clergy and the kings. It is from the statutes, indeed, which Alfred, Canute, and other monarchs passed for the prevention of magical practices, that we chiefly know their nature and extent. *Wiglaer*, a wizard, and *wicoa*, a witch, are persons severely denounced. Penalties are enjoined if any one should destroy another by *wiccecraft*. They appear to have used philters; for it is declared a crime in any one to use witchcraft, or potions to produce another's love. Canute enjoins his people not to worship fire or floods, wells or stones, or any sort of tree; not to frame death-spells, either by lot or otherwise; and not to effect anything by phantoms. Wizards, we also learn, pretended to the power of letting loose tempests, and controlling the visible operations of nature.

The introduction of Christianity, as has been mentioned, failed to dissipate the familiar superstitions of the English; a circumstance which can excite no surprise, as no pains were taken to enlighten the understandings of the people, or make them acquainted with the true causes of natural phenomena. We accordingly find that from the seventh to the sixteenth century the belief in demons, spirits, lubber-fiends, and elves, of every shade and character, prevailed without intermission, and with no further challenge from the clergy than as being individually manifestations of the devil, on whom now the whole load of superstition was based. One goblin in particular formed the theme of innumerable legends. What was his name originally in continental Europe, whence he emigrated with the Anglo-Saxons, is of little consequence; in England he became known by the title of Father Rush, from a belief that he had on one occasion personated a monk or friar, and, to serve his own malignant purposes, had in that capacity long imposed on a religious brotherhood; afterwards, this appellation went out of repute, and he was popularly known and feared by the familiar name of Robin Goodfellow, and performed many useful services in the rural districts. It is not a little strange that both monks and clergy sanctioned these fancies, and increased their number by the propagation of legends, which we venture to say could not now receive the approbation of a single individual, lay or clerical, in England. Of these it is only necessary to mention the absurd stories which were fabricated and circulated respecting Dunstan, abbot of Glastonbury, and afterwards archbishop of Canterbury, who died in the year 988. When a boy, he is stated to have studied theology so sedulously as to reduce him to the point of death, when he was suddenly restored by some divine medicine sent to him by an angel in a storm. So extraordinary a circumstance could not but demand grateful thanksgivings, and Dunstan started from his bed, and ran with full speed towards the church. Satan met him in the way, surrounded with numerous black dogs, and endeavoured to defeat his pious intention. But Dunstan was not to be overcome; he instantly prayed for ability, and was enabled to cudgel the devil and his black dogs so effectually, that they left him and the angel together; the latter of whom, finding the church door fastened, took up the pious youth in his arms, and conveyed him to his devotions through the roof. Another time the devil attempted to intrude himself upon St Dunstan's studies in his laboratory; but the saint speedily punished his impertinence, by taking from the fire his tongs, which were red hot, and with them seized the nose of the fiend, who was thereupon glad to make his escape. It is lamentable to think how such vain imaginations should have so long weighed upon the understandings of the people, and engrafted a habitual dread of the supernatural, which till this day exerts an influence over the untutored mind.

## Fairies.

Among the various supernatural beings to whom the ignorance and credulity of mankind have given an imaginary existence, the fairies occupy a prominent place, and are especially worthy of notice. The characters of different classes of spirits have become so mingled and confounded together in the lapse of time, that it is difficult to define individual species with correctness and precision; but there is one characteristic which appears to distinguish the fairy from every other being of a similar order. Most spirits could contract and diminish their bulk at will; but the fairy alone seems to have been regarded as essentially small in size. The majority of other spirits, also, such as dwarfs, brownies, and the like, are represented as deformed creatures, whereas the fairy has almost uniformly been described as a beautiful miniature of the human being, perfect in face and form. These points of distinction, with a dress of pure green, are the principal features which serve to mark the personal individuality of the fairies as a supernatural race.

The origin of the fairy superstition is ascribed by most writers to the Celtic people; but the blending of the Gothic tribes with the Celts led to the admixture of many attributes of the northern spirits with those proper to the fairies. Thus the latter race, which appears to have been intrinsically good and benevolent, has been gifted with attributes of the very opposite kind, borrowed from the trolls and elves of the north. In Scotland, and other countries where the Celtic traditions predominated, the fairies retained in part the original and better features of their character, and were usually called the Good Neighbours, or the Men of Peace; but even there their character was deteriorated by a considerable leaven of elfin or dwarfish malignancy. This evil part of their nature caused much annoyance to mankind, and more especially their propensity to the kidnapping of human beings. Unchristened infants were chiefly liable to this calamity, but sometimes adult men and women were also carried off. The reason for these abductions is to be found, according to the authorities on this subject, in the necessity which the fairies lay under of paying 'kane,' as it was called, to the master-fiend; or, in other words, of yielding up one of their number septennially into his hands by way of tribute. They greatly preferred on such occasions to make a scape-goat of some member of the human family. They also carried off young married women to be nurses to their infants; and in Ireland, at this day, when a young woman falls a victim to puerperal disease, the more ignorant of the country people assert that she has been removed for this purpose.

The necessity for the latter kind of kidnapping shows the fairies to have been *family* people. They are always represented as living, like mankind, in large societies, and under a monarchical form of government. The Salique law seems to have had no countenance among them; for we more often hear of fairy queens than of fairy kings, though both are frequently spoken of. The Land of Faerie was situated somewhere under ground, and there the royal fairies held their court. In their palaces all was beauty and splendour. Their pageants and processions were far more magnificent than any that Eastern sovereigns could get up, or poets devise. They rode upon milk-white steeds. Their dresses, of brilliant green, were rich beyond conception; and when they mingled in the dance, or moved in procession among the shady groves, or over the verdant lawns of earth, they were entertained with delicious music, such as mortal lips or hands never could emit or produce. At the same time most of the legendary tales on the subject represent these splendours as shadowy and unsubstantial. When the eye of a seer, or any one gifted with supernatural powers, was turned upon the fairy pageantries or banquets, the illusion vanished. Their seeming treasures of gold and silver became slate-stones, their stately halls became damp caverns, and they themselves, from being miniature models of human

beauty, became personifications of fantastic ugliness. In short, the Fairy Eden was a day-dream—a thing of show without substance.

This is the general account given of the fairy state, but few of the legends on the subject agree on all points. From a very early period, however, every fairy annalist concurred in giving to the king and queen of the fairies the names of Oberon and Titania. Oberon is the Elb-rich, or Rich Elf, of the Germans, and was endowed with his modern name, as well as with new attributes, by the old French romancers, who represented him as a tiny creature of surpassing loveliness, with a crown of jewels on his head, and a horn in his hand that set all who heard it to the dancing.

It was the belief that unchristened children were peculiarly liable to be carried off by the fairies, who sometimes left little changelings of their own blood in place of the infants of mortal kind. Ben Jonson, in his 'Sad Shepherd,' makes the tending and nurture of human changelings to be one of the favourite elfin employments:—

'There, in the stocks of trees, white fays do dwell,  
And span-long elves, that dance about a pool,  
With each a little changeling in their arms.'

Various charms were used in Scotland for the restoration of stolen children. The most efficacious was believed to be the *roasting* of the superstitious child upon live embers, when it was understood that the false infant would disappear, and the true one be left in its place. It is to be hoped that this cruel and monstrous practice was seldom followed. The possession of what are called *toadstones* was also held to be an efficient preservative against the abduction of children by the fairies. In Waldron's 'Account of the Isle of Man' we find various stories of children kidnapped by the fairies. In one case, where a woman had given birth to a child, her attendants were enticed from the house by a cry of 'Fire!' and while they were out, the child was taken from the helpless mother by an invisible hand; but the sudden re-entry of some of the gossips compelled the fairies to drop the child, and it was found sprawling on the threshold. The fairies, who seemed to have taken a particular liking to this woman's offspring, tried to carry off her second child in the same way; but failed again. On a third trial they succeeded, and left behind them a changeling, a withered and deformed creature, which neither spoke nor walked during an existence of nine years, and ate nothing but a few herbs. It is to be feared that this changeling superstition must have been the cause of much deplorable cruelty. That very member of a family who, from natural misfortunes and defects, required the kindest tending, would but too often be neglected and wretchedly misused, on the plea of its being an alien. We may smile at many of the credulous fancies respecting the fairies; but there are in this order of superstitions, as in almost all others, some points which strongly exhibit to us the baleful effects inevitably attendant upon ignorance of every kind.

Numberless stories of a ridiculous kind have been told relative to the intercourse of the fairies with mankind. Some of the poor creatures arraigned in Scotland in past times for witchcraft, admitted having had correspondence with the fairies. There can be little doubt that these wretched beings, whom the *torture* forced into the confession of some kind or other of supernatural traffic, were induced to admit an association with fairies, in the hope that this would be looked upon as less sinful than a league with the enemy of mankind. The trials of Bessie Dunlop and Alison Pearson, in the years 1676 and 1688, illustrate this statement. Bessie Dunlop avowed that her familiar was one Thome Reid, the ghost of a soldier slain at Pinkie in 1547, and who after his death seems to have become an inmate of Elf-land. She related that this Thome Reid, who appeared frequently to her in the likeness of an elderly man, gray-coated and gray-bearded, wished her to go with him to

the fairy country, and gave her herbs to cure various diseases. He even once brought to her the queen of the fairies, who, to the confusion of poetry, was a fat woman, fond of ale, and, in short, most unlike the Titania of romance. Alison Pearson also admitted her familiarity with the fairies, from whom she frequently received herbs for the cure of disease. It is remarkable that Patrick Adamson, an able scholar and divine, who was created archbishop of St Andrews by James VI., actually took the medicines prescribed by this poor woman, in the hope that they would transfer an illness with which he was seized to the body of one of his horses. This feat, it was believed, was accomplished by the supernatural prescription. The unfortunate women who confessed to these things, were deceived in the expectation which led to the act. They could not so save themselves: they were both convicted, and perished at the stake.

It may not be improper in this place to allude to the fancies of the poets on the subject of the fairies. Shakespeare stands pre-eminent in this department. His 'Midsummer Night's Dream' is a poem of exquisite beauty, and one corresponding in every respect with the delicately-fanciful nature of the subject. In 'Romeo and Juliet' he has also described an important fairy, Queen Mab, who has almost dethroned Titania of late years. Mr Tennant's 'Anster Fair' has been of great avail to the fame of Mab. Whoever chooses to consult Drayton and the poets mentioned, will have the pleasure of observing and enjoying the exercise of poetical fancy of the highest order on the subject of fairies.

The superstitions now described are not yet extinct in the British Islands. In Ireland, the Scottish Highlands, and Wales, in particular, the fairies are yet objects of common belief. Education has not yet shed its enlightening influence there, and by education alone can the darkness of superstition be dispelled. This is almost a truism; for superstition and ignorance are nothing else than equivalent terms. The spirit is abroad, however, which will extinguish this remnant of barbarism, and it is consoling to think so, for the ills which have flowed from this source are numberless.

WITCHCRAFT.

A belief that certain individuals possessed magical powers, and could exercise a supernatural influence over their fellow-creatures, existed in ancient Rome, and those who practised, or rather pretended to exercise, such arts, were punishable by the civil magistrate. It is to be observed that neither among the Romans nor the Pagan nations of northern Europe, was witchcraft deemed an offence against religion; in some instances, indeed, the witch was supposed to derive her powers from spirits friendly to mankind, and her profession, though feared, was held in honour by her infatuated dupes. Upon the introduction of Christianity, witchcraft assumed a new form, though retaining all its old attributes. Instead of ascribing the supernatural powers of the practitioner to the gods, to Odin, to spirits of good or evil qualities, or to supposed mysteries in nature, the people imputed them to the great fallen spirit mentioned in Scripture. This potent being, from a wicked desire to destroy all that was good and hopeful in man's destiny, was believed to enter into a compact with the aspirant witch, in which, for an irrevocable assignment of her soul at death, he was to grant all her wishes, and assist in all her malevolent projects. These new features in witchcraft, as we shall speedily perceive, thoroughly changed and prodigiously extended the superstition throughout Europe. From being rather a sportive kind of jugglery, or trick in practical magic, and at most only a civil offence, it was now recognised as a crime of the deepest dye, meriting the most severe chastisement which the ecclesiastical and civil power could inflict.

We must here notice, however, that the demon or master-fiend of the witchcraft legends was a very different being from that great fallen spirit, held, in a graver view of things, so deeply to influence the best

interests of humanity. As this superstition gained force in the Christian world, which it did by slow and successive steps through the whole of the middle ages, or from the fifth century till about the fifteenth, the devil—for it is impossible to avoid the mention of this emphatic name, disagreeable as it is commonly said to be to ears polite—gradually lost many of the former features of his character; or, rather, a different being was substituted for him, combining the characteristics of the Scandinavian Lokke with those of a Satyr of the heathen mythology—a personage equally wicked and malicious as the sterner spirit of evil, but rendered ludicrous by a propensity for petty trickery, and by such personal endowments as a pair of horns, a cow's tail, and cloven feet. There can be no doubt that the demon of the middle ages borrowed these attributes from his human representatives in the old mysteries and plays, where a laudable endeavour was made to make the evil one as ugly as possible. We are told, it is true, that he could at will assume any specious disguise that suited him, but the eye of the initiated observer could readily detect the 'cloven foot'—or, in other words, penetrate his true character. Such as he was, he played an important part in the annals of modern witchcraft, which was supposed to rest entirely on the direct and personal agency of himself and the imps commissioned by him. Nor was this supposition confined to the illiterate, or to persons of peculiarly credulous temperament. Authors, distinguished for sense and talent, record with great seriousness that the devil once delivered a course of lectures on magic at Salamanca, habited in a professor's gown and wig; and that at another time he took up house in Milan, lived there in great style, and assumed, rather imprudently one would say, the suspicious, yet appropriate title of the 'Duke of Mammon.' Even Luther entertained similar notions about the fiend; and in fact thought so meanly of him, as to believe that he could come by night and steal nuts, and that he cracked them against the bedposts, for the solacement of his monkey-like appetite.

The powers ascribed to this debased demon were exceedingly great. The general belief was, that through his agency storms at sea and land could at all seasons be raised; that crops could be blighted, and cattle injured; that bodily illnesses could be inflicted on any person who was the object of secret malice; that the dead could be raised to life; that witches could ride through the air on broomsticks, and transform themselves into the shapes of cats, hares, or other animals, at pleasure. An old writer, speaking of the powers of witches, says—'1. Some work their bewitchings only by way of invocation or imprecation. They wish it, or will it; and so it falls out. 2. Some, by way of emissary, sending out their imps, or familiars, to cross the way, jumble, affront, flash in the face, barke, howle, bite, scratch, or otherwise infest. 3. Some by inspecting, or looking on, or to glare, or peep at with an envious and evil eye. 4. Some by a hollow muttering or mumbling. 5. Some by breathing and blowing on. 6. Some by cursing and banning. 7. Some by blessing and praising. 8. Some revengefully, by occasion of ill turnes. 9. Some ingratelully, and by occasion of good turnes. 10. Some by leaving something of theirs in your house. 11. Some by getting something of yours into their house. 12. Some have a more speciall way of working by severall elements—earth, water, ayre, or fire. But who can tell all the manner of wayes of a witch's working; that works not only darkly and closely, but variously and versatilly, as God will permit, the devil can suggest, or the malicious hag devise to put in practice?'

In the present age of comparative intelligence, it is difficult to understand how human beings could be so deplorably ignorant as to entertain such a gross superstition. We must, however, recollect that the belief was greatly fostered by religious impressions, and that it was long considered a mark of impiety to doubt the existence of witches. Various other circumstances helped to cherish and magnify the error. The true causes of the majority of natural phenomena were

unknown. The nature of the atmosphere, and of certain meteoric appearances—of the laws which regulate storms at sea, and tides—of human maladies and their remedies—were enveloped in obscurity. Natural causes being unknown, and the very doctrine of them unacknowledged, the weak and easily-terrified mind flew to the conclusion that all evil proceeded from a power malignant to man, and that, by certain impious dealings, it was possible for man himself to direct that power against his neighbour.

The superstition seems to have approached its height about the end of the fifteenth century. In his bull of 1484, Pope Innocent charged inquisitors and others to discover and destroy all such as were guilty of witchcraft. This commission was put into the hands of a wretch called Sprenger, with directions that it should be put in force to its fullest extent. Immediately there followed a regular form of process and trial for suspected witches, entitled *Malleus Maleficarum*, or a Hammer for Witches, upon which all judges were called scrupulously to act. The edict of 1484 was subsequently enforced by a bull of Alexander VI. in 1494, of Leo X. in 1521, and of Adrian VI. in 1522—each adding strength to its predecessor, and the whole serving to increase the agitation of the public mind upon the subject. The results were dreadful. A panic fear of witchcraft took possession of society. Every one was at the mercy of his neighbour. If any one felt an unaccountable illness, or a peculiar pain in any part of his body, or suffered any misfortune in his family or affairs, or if a storm arose, and committed any damage by sea or land, or if any cattle died suddenly, or, in short, if any event, circumstance, or thing occurred out of the ordinary routine of daily experience, the cause of it was witchcraft. To be accused was to be doomed; for it rarely happened that proof was wanting, or that condemnation was not followed by execution. Armed with the *Malleus Maleficarum*, the judge had no difficulty in finding reasons for sending the most innocent to the stake. If the accused did not at once confess, they were ordered to be shaved and closely examined for the discovery of devil's marks; it being a tenet in the delusion that the devil, on inaugurating any witch, impressed certain marks on her person; and if any strange mark was discovered, there remained no longer any doubt of the party's guilt. Failing this kind of evidence, torture was applied, and this seldom failed to extort the desired confession from the unhappy victim. A large proportion of the accused witches, in order to avoid these preliminary horrors, confessed the crime in any terms which were dictated to them, and were forthwith led to execution. Other witches, as has been said, seemed to confess voluntarily, being probably either insane persons, or feeble-minded beings, whose reason had been distorted by brooding over the popular witchcraft code. A few extracts from the work of Dr Hutchinson will show the extent of these miserable proceedings:—

A. D. 1485.—Cumanas, an inquisitor, burnt forty-one poor women for witches, in the county of Burlia, in one year. He caused them to be shaven first, that they may be searched for marks. He continued the prosecutions in the year following, and many fled out of the country.

About this time, Alciat, a famous lawyer, in his *Parerga*, says, "One inquisitor burnt a hundred in Piedmont, and proceeded daily to burn more, till the people rose against the inquisitor, and chased him out of the country."

A. D. 1488.—A violent tempest of thunder and lightning in Constance destroyed the corn for four leagues round. The people accused one Anne Mindelin, and one Agnes, for being the cause of it. They confessed, and were burnt.

About this time H. Institor says, one of the inquisitors came to a certain town that was almost desolate with plague and famine. The report went that a certain woman, buried not long before, was eating up her winding-sheet, and that the plague would not cease till

she had made an end of it. This matter being taken into consideration, Scultetus, with the chief magistrate of the city, opened the grave, and found that she had indeed swallowed and devoured one-half of her winding-sheet. Scultetus, moved with horror at the thing, drew out his sword and cut off her head, and threw it into a ditch, and immediately the plague ceased! and the inquisition sitting upon the case, it was found that she had long been a reputed witch.

A. D. 1524.—About this time a thousand were burned in one year, in the diocese of Como, and a hundred per annum for several years together.'

From other authorities it is learned that the devastation was as great in Spain, France, and northern Germany, as it was in the Italian states. About the year 1515, five hundred witches were burned in Geneva in three months, and in France many thousands. An able writer in the *Foreign Quarterly Review* (No. XI. 1830), sums up the following particulars respecting the executions for witchcraft in some of the German states:—

'In Germany, to which indeed the bull of Innocent bore particular reference, this plague raged to a degree almost inconceivable. Bainberg, Paderborn, Wurtzburg, and Treves were its chief seats, though for a century and a-half after the introduction of the trials under the commission, no quarter of that great empire was free from its baneful influence. A catalogue of the executions at Wurtzburg for the period from 1627 to February 1629, about two years and two months, is printed by Hauber in the conclusion of his third volume of the *Acta et Scripta Magica*. It is regularly divided into twenty-nine burnings, and contains the names of 157 persons, Hauber stating at the same time that the catalogue is not complete. It is impossible to peruse this list without shuddering with horror. The greater part of this catalogue consists of old women or foreign travellers, seized, as it would appear, as foreigners were at Paris during the days of Marat and Robespierre: it contains children of twelve, eleven, ten, and nine years of age; fourteen vicars of the cathedral; two boys of noble families, the two little sons of the senator Stolzenburg; a stranger boy; a blind girl; Gobel Babelin, the handsomest girl in Wurtzburg, &c. And yet, frightful as this list of 157 persons executed in the short space of two years appears, the number is not (taking the population of Wurtzburg into account) so great as the Lindheim process from 1660 to 1664; for in that small district, consisting at the very utmost of 600 inhabitants, thirty persons were condemned and put to death, making a twentieth part of the whole population consumed in four years.

How dreadful are the results to which these data lead! If we take 157 as a fair average of the executions at Wurtzburg (and the catalogue itself states that the list was by no means complete), the amount of executions there in the course of the century preceding 1628 would be 15,700. We know that from 1610 to 1660 was the great epoch of the witch trials, and that so late as 1749 Maria Renata was executed at Wurtzburg for witchcraft; and though in the interval between 1660 and that date, it is to be hoped that the number of these horrors had diminished, there can be little doubt that several thousands fall to be added to the amount already stated. If Bainberg, Paderborn, Treves, and the other Catholic bishoprics, whose seal was not less ardent, furnished an equal contingent, and if the Protestants, as we know, actually vied with them in the extent to which these cruelties were carried, the number of victims from the date of Innocent's bull to the final extinction of these prosecutions, must considerably exceed 100,000 in Germany.'

#### Witchcraft in Scotland.

The mania respecting witchcraft, which sprang up into vigour throughout southern Europe in consequence of the edicts of Innocent and Leo, spread in time to Scotland, and acquired strong possession of the public mind during the reign of Queen Mary. At that period an act was passed by the Scottish Parliament for the

## SUPERSTITIONS.

suppression and punishment of witchcraft; but this only served, as the papal bulls had done, to confirm the people in their maniacal credulity, and to countenance and propagate the general delusion. In terms of these ill-judged statutes, great numbers of persons, male as well as female, were charged with having intercourse with the devil, convicted, and burned on the Castlehill of Edinburgh and elsewhere. This continued during the earlier part of the reign of James VI., whose mind, unfortunately for the more aged of the female part of his subjects, was deeply impressed with the flagrant nature of the crime of witchcraft. In 1590, James, it is well known, made a voyage to Denmark to see, marry, and conduct home in person his appointed bride, the Princess Anne. Soon after his arrival, a tremendous witch conspiracy against the happy conclusion of his homeward voyage was discovered, in which the principal agents appeared to be persons considerably above the vulgar. One was Mrs Agnes Sampson, commonly called the *Wise Wife of Keith* (Keith being a village in East-Lothian), who is described as 'grave, matron-like, and settled in her answers.' On this occasion, the king was induced by his peculiar tastes to engage personally in the business of judicial investigation. He had all the accused persons brought before himself for examination, and even superintended the tortures applied to them to induce confession. The statements made by these poor wretches form a singular tissue of the ludicrous and horrible in intimate union.

'The said Agnes Sampson was after brought again before the king's majesty and his council, and being examined of the meetings and detestable dealings of those witches, she confessed that upon the night of All-Hallow-even, she was accompanied, as well with the persons aforesaid, as also with a great many other witches, to the number of two hundred, and that all they together went to sea, each one in a riddle, or sieve, and went in the same very substantially, with flagons of wine, making merrie, and drinking by the way in the same riddles or sieves, to the kirk of North Berwick in Lothian; and that after they had landed, took hands on the land, and danced this reil, or short daunce, singing all with one voice—

"Cummer, goe ye before, cummer, goe ye;  
Gif ye will not goe before, cummer, let me."

At which she confessed that Geillis Duncan did goe before them, playing this reil or daunce upon a small trump, called a Jew's harp, until they entered into the kirk of North Berwick. These made the king in a wonderful admiration, and he sent for the said Geillis Duncan, who upon the like trump did play the said daunce before the king's majesty, who, in respect of the strangeness of these matters, took great delight to be present at their examinations.'

In the sequel of Agnes Sampson's confession we find some special reasons for the king's passionate liking for these exhibitions, in addition to the mere love of the marvellous. The witches pandered to his vanity on all occasions, probably in the vain hope of mitigating their own doom. Agnes Sampson declared that one great object with Satan and his agents was to destroy the king; that they had held the great North Berwick convention for no other end; and that they had endeavoured to effect their aim on many occasions, and particularly by raising a storm at sea when James came across from Denmark. 'The witches demanded of the divell why he did beare such hatred to the king? who answered, by reason the king is the greatest enimie hee hath in the world.' Such a eulogy, from such a quarter, could not but pamper the conceit of 'the Scottish Solomon.'

The following further points in the deposition of Agnes Sampson are worthy of notice:—*Item*, She went with the witch of Carrieburn, and other witches, to the kirk of Newton, and taking up dead folks and jointing them [cutting off fingers, &c.], made enchanted powders for witchcraft. *Item*, She went with other witches in a boat, the devil going before them like a rick of hay.

*Item*, The devil, in the shape of a dog, gave her responses concerning her laird's recovery, and endeavoured to put awa ane of the ladies' daughters. *Item*, She raised a universal great storm in the sea when the queen was coming to Scotland, and wrote a letter to that effect to a witch in Leith. *Item*, She used this prayer in the healing of sickness:—

"All kinds of ill that ever may be," &c.

The repetition of these and such-like verses by the confessing witches, has been matter of frequent surprise. But it must be remembered that a code of witchcraft, extensively known and accredited, existed at that day, regular forms and rules for its exercise having been laid down in the course of time. It must be recollected, also, that these poor creatures, though guiltless of all supernatural intercourse, had really pretended to the gift of healing by charms and incantations in many cases, and had to invent or learn formulas for the purpose. Besides, we find these doggerel scraps chiefly in the revelations of Agnes Sampson. She, it is stated, could write, and of course could read also; hence she is to be regarded as a person who had had superior opportunities for acquiring a knowledge of the witchcraft code, as well as superior capabilities for filling up deficiencies on the spur of the moment. In her confession she implicated one Dr Fian, otherwise called John Cunningham, master of the school at Salt pans in Lothian, a man whose story may be noticed at some length, as one of the most curious and instructive in the whole annals of Scottish witchcraft.

Mrs Sampson deposed that Dr Fian was always a prominent person at the witch-meetings, and Geillis Duncan, the marvellous trump-player, confirmed this assertion. Whether made through heedlessness or malice, these averments decided Fian's fate. He was seized, and after being 'used with the *accustomed pains* provided for those offences inflicted upon the rest, first, by *throwing of his head with a rope*, whereat he would confess nothing; and secondly, being urged 'by fair means to confesse his follies,' which had as little effect; 'lastly, hee was put to the most severe and cruell paine in the world, called the booties, when, after he had received three strokes, being inquired if he would confesse his actes and wicked life, his tongue would not serve him to speake; in respect whereof, the rest of the witches willed to search his tongue, under which was founde two pinnes thrust up into the heade; whereupon the witches did say, now is the charme stinted, and showed that those charmed pins were the cause he could not confesse anything; then was he immediately released of the booties, brought before the king, and his confession was taken.' Appalled by the cruel tortures he had undergone, Fian seems now only to have thought how he could best get up a story that should bring him to a speedy death. He admitted himself to be the devil's 'register,' or clerk, who took the oaths from all witches at their initiation, and avowed his having bewitched various persons. In proof of the latter statement he instanced the case of a gentleman near Salt pans, whom he had so practised upon, he said, that the victim fell into fits at intervals. This person, who seems to have been either a lunatic or afflicted with St Vitus's dance, was sent for, and 'being in his majesty's chamber, suddenly hee gave a great scritch, and fell into madnesse, sometimes bending himself, and sometimes capping so directly up, that his heade did touch the ceiling of the chamber, to the great admiration of his majesty.' On these and other accounts Dr Fian was sent to prison, but he contrived soon after to escape from it. 'By means of a hot and harde pursuit,' he was retaken, and brought before the king, to be examined anew. But the unfortunate man had had time to think, and like Crammer under somewhat similar circumstances, resolved to retract the admissions which the weakness of the body had drawn from him, and to suffer anything rather than renew them. He boldly told this to the king; and James, whom these records make us regard with equal contempt and

indignation, ordered the unfortunate man to be subjected to the following most horrible tortures:—' His nails upon all his fingers were riven and pulled off with an instrument called in Scottish a *turkas*, which in England are called a payre of pincers, and under everie mayle there was thrust in two needles over, even up to the heades; at all which tormentes, notwithstanding, the doctor never shrunk a whit, neither would he then confesse it the sooner for all the tortures inflicted on him. Then was hee, with all convenient speed, by commandement, conveyed again to the torment of the bootes, wherein he continued a long time, and did abide so many blowes in them, that his legges were crusht and beaten together as small as might bee, whereby they were make unserviceable for ever.' Notwithstanding all this, such was the strength of mind of the victim, or, as King James termed it, 'so deeply had the devil entered into his heart,' that he still denied all, and resolutely declared that 'all he had done and said before was only done and said for fear of the paynes which he had endured.' As, according to this fashion of justice, to confess or not to confess was quite the same thing, the poor schoolmaster of Salt-pans was soon afterwards strangled, and then burned on the Castlehill of Edinburgh (January 1591).

Much about the same time that Agnes Sampson made her confessions, some cases occurred, showing that witchcraft was an art not confined to the vulgar. A woman of high rank and family, Catherine Ross, Lady Fowlis, was indicted at the instance of the king's advocates for the practice of witchcraft. On inquiry, it was clearly proved that this lady had endeavoured, by the aid of witchcraft and poisons, to take away the lives of three or more persons who stood between her and an object she had at heart. She was desirous to make young Lady Fowlis possessor of the property of Fowlis, and to marry her to the Laird of Balnagowan. Before this could be effected, Lady Fowlis had to cut off her sons-in-law, Robert and Hector Munro, and the young wife of Balnagowan, besides several others. Having consulted with witches, Lady Fowlis began her work by getting pictures of the intended victims made in clay, which she hung up, and shot at with arrows shod with flints of a particular kind, called elf-arrow heads. No effect being thus produced, this really abandoned woman took to poisoning ale and dishes, none of which cut off the proper persons, though others who accidentally tasted them lost their lives. By the confession of some of the assistant hags, the purposes of Lady Fowlis were discovered, and she was brought to trial; but a local or provincial jury of dependants acquitted her. One of her purposed victims, Hector Munro, was then tried in turn for conspiring with witches against the life of his brother George. It was proved, in evidence, that a curious ceremony had been practised to effect this end. Hector, being sick, was carried abroad in blankets, and laid in an open grave, on which his foster-mother ran the breadth of nine riggs, and returning, was asked by the chief attendant witch, 'Which she chose should live, Hector or George?' She answered, 'Hector.' George Munro did die soon afterwards, and Hector recovered. The latter was tried, but, like Lady Fowlis, was acquitted by a provincial jury.

These disgraceful proceedings were not without their parallel in other families of note of the day. Euphemia Macalzean, daughter of an eminent judge, Lord Clifton-hall, was burned at the stake in 1591, having been convicted, if not of witchcraft, at least of a long career of intercourse with pretenders to witchcraft, whom she employed to remove obnoxious persons out of her way—tasks which they accomplished by the very simple means of poisoning, where they did accomplish them at all. The jury found this violent and abandoned woman, for such she certainly was, guilty of participation in the murder of her own godfather, of her husband's nephew, and another individual. They also found her guilty of having been at the Wise Woman of Keith's great witch-convention of North Berwick; but every witch of the day was compelled to admit having been there, out of

compliment to the king, to whom it was a source of agreeable terror to think himself of so much importance as to call for a solemn convocation of the powers of evil to overthrow him. Euphemia Macalzean was 'burnt in assis, quick, to the death.' This was a doom not assigned to the less guilty. Alluding to cases of this latter class, a writer (already quoted) in the Foreign Quarterly Review remarks, 'In the trials of Bessie Roy, of James Reid, of Patrick Currie, of Isobel Grierson, and of Grizel Gardiner, the charges are principally of taking off and laying on diseases either on men or cattle; meetings with the devil in various shapes and places; raising and dismembering dead bodies for the purpose of enchantments; destroying crops; scaring honest persons in the shape of cats; taking away women's milk; committing housebreaking and theft by means of enchantments; and so on. South-running water, salt, rowan-tree, enchanted flints (probably elf-arrow heads), and doggerel verses, generally a translation of the Creed or Lord's Prayer, were the means employed for effecting a cure.' Diseases, again, were laid on by forming pictures of clay or wax; by placing a dead hand, or some mutilated member, in the house of the intended victim; or by throwing enchanted articles at his door. A good purpose did not save the witch; intercourse with spirits in any shape being the crime.

Of course in the revelations of the various witches inconsistencies were abundant, and even plain and evident impossibilities were frequently among the things averred. The sapient James, however, in place of being led by these things to doubt the whole, was only strengthened in his opinions, it being a maxim of his that the witches were 'all extreme liars.' Other persons came to different conclusions from the same premises; and before the close of James's reign, many men of sense began to weary of the torturings and incriminations that took place almost every day, in town or country, and had done so for a period of thirty years (betwixt 1590 and 1620). Advocates now came forward to defend the accused, and in their pleadings ventured even to arraign some of the received axioms of 'Daemonologie' laid down by the king himself, in a book bearing that name. The removal of James to England moderated, but did not altogether stop the witch prosecutions. After his death they slackened more considerably. Only eight witchcraft cases are on the Record as having occurred between 1625 and 1640 in Scotland, and in one of these cases, remarkable to tell, the accused escaped. The mania, as it appears, was beginning to wear itself out.

As the spirit of puritanism gained strength, however, which it gradually did during the latter part of the reign of Charles I., the partially-cleared horizon became again overcast, and again was this owing to ill-judged edicts, which, by indicating the belief of the great and the educated in witchcraft, had the natural effect of reviving the frenzy among the flexible populace. The General Assembly was the body in fault on this occasion, and from this time forward the clergy were the great witch-hunters in Scotland. The Assembly passed condemnatory acts in 1640, 1643, 1644, 1645, and 1649, and with every successive act the cases and convictions increased, with even a deeper degree of attendant horrors than at any previous time. 'The old impossible and abominable fancies,' says the review formerly quoted, 'of the *Malleus* were revived. About thirty trials appear on the Record between 1649 and the Restoration, only one of which appears to have terminated in an acquittal; while at a single circuit, held at Glasgow, Stirling, and Ayr, in 1659, seventeen persons were convicted and burnt for this crime.'

It must be remembered, however, that the phrase 'on the Record' alludes only to justiciary trials, which formed but a small proportion of the cases really tried. The justiciary lists take no note of the commissions perpetually given by the privy-council to resident gentlemen and clergymen to try and burn witches in their respective districts. These commissions executed people over the whole country in multitudes. Wodrow, Lamont,

## SUPERSTITIONS.

Mercer, Whitelocke, and other chroniclers, prove this but too satisfactorily.

The clergy continued, after the Restoration, to pursue these imaginary criminals with a zeal altogether deplorable. The Justiciary Court condemned twenty persons in the first year of Charles II.'s reign (1661); and in one day of the same year the council issued fourteen new provincial commissions, the aggregate doings of which one shudders to guess at. To compute their condemnations would be impossible, for victim after victim perished at the stake, unnamed and unheard of. Morayshire became at this particular period the scene of a violent fit of the great moral frenzy, and some of the most remarkable examinations signalling the whole course of Scottish witchcraft took place in that county. The details, though occasionally ludicrous from their absurdity, are too horrible for narration in the present pages.

The popular frenzy seems to have exhausted itself by its own virulence in 1661-62; for an interval of six years subsequently elapsed without a single justiciary trial for the crime of witchcraft, and one fellow was actually whipped for charging some person with it. After this period, the dying embers of the delusion only burst out on occasions, here and there, into a momentary flame. In 1678, several women were condemned, 'on their own confession,' says the Register; but we suspect this only means in reality that one malicious being made voluntary admissions involving others, as must often have been the case, we fear, in these proceedings. Scattered cases took place near the beginning of the eighteenth century; such as those at Paisley in 1697, at Pittenweem in 1704, and at Spott about the same time. It is curious that as something like direct evidence became necessary for condemnation, that evidence presented itself, and in the shape of possessed or enchanted young persons, who were brought into court to play off their tricks. The most striking case of this nature was that of Christian Shaw, a girl about eleven years old, and the daughter of Mr Shaw of Bargarran in Renfrewshire. This wretched girl, who seems to have been an accomplished hypocrite, young as she was, quarrelled with a maid-servant, and to be revenged, fell into convulsions, saw spirits, and, in short, feigned herself bewitched. To sustain her story, she accused one person after another, till not less than twenty were implicated, some of them children of the ages of twelve and fourteen! They were tried on the evidence of the girl, and five human beings perished through her malicious impostures. It is remarkable that this very girl afterwards founded the thread manufactory in Renfrewshire. From a friend who had been in Holland, she learned some secrets in spinning, and putting them skillfully in practice, she led the way to the extensive operations carried on in that department of late years. She became the wife of the minister of Kilmaura, and it is to be hoped, had leisure and grace to repent of the wicked misapplication, in her youth, of those talents which she undoubtedly possessed.

The last justiciary trial for witchcraft in Scotland was in the case of Elspeth Rule, who was convicted in 1708, and—banished. The last regular execution for the crime is said to have taken place at Dornoch in 1722, when an old woman was condemned by David Ross, sheriff of Caithness. But we fear the provincial records of the north, if inquired into, would show later deaths on this score. However, here may be held to end the tragical part of the annals of Scottish witchcraft. The number of its victims, for reasons previously stated, it would be difficult accurately to compute; but the black scroll would include, according to those who have most attentively inquired into the subject, upwards of FOUR THOUSAND persons! And by what a fate they perished! Cruelly tortured while living, and dismissed from life by a living death amid the flames! And for what? For an impossible crime! And who were the victims, and who the executioners? The victims, in by far the majority of cases, were the aged, the weak, the deformed, the lame, and the blind; those to whom

nature had been ungentle in her outward gifts, or whom years and infirmities had doomed to poverty and wretchedness; exactly that class of miserable beings, in short, for whom more enlightened times provide houses of refuge, and endow charitable institutions, aiming, in the spirit of true benevolence, to supply to them that attention and support which nature or circumstances have denied them the power of procuring for themselves. Often, too, was the victim a person distinguished by particular gifts and endowments; gifts bestowed by the Creator in kindness, but rendered fatal to the possessor by man. These were the victims of witchcraft. The executioners were the wisest and greatest of their time. Men distinguished above their fellows for knowledge and intelligence, ministers of religion and of the laws, kings, princes, and nobles—these, and such as these, judged of the crime, pronounced the doom, and sent the poor victims of delusion to the torture, the stake, and the scaffold.

### Witchcraft in England.

Witchcraft was first denounced in England, by formal and explicit statutes, in the year 1541, in the reign of Henry VIII. Previously to that time many witch-trials had taken place, and severe punishments had even been inflicted on the parties concerned; but this was occasioned by the direction of the arts of sorcery, in these particular instances, against the lives and wellbeing of others, and not from the legal criminality of such arts themselves. Shakspeare has made some early cases of this nature familiar to us, and in particular that of the Duchess of Gloucester, who, for conspiring with witches against the life of the reigning sovereign, Henry VI., was compelled to do public penance, and imprisoned for life. But, as has been said, the mode of prosecuting the guilty purpose was here altogether a subsidiary matter. If a person waved his hat three times in the air, and three times cried 'Buzz!' under the impression that by that formula the life of another might be taken away, the old law and law-makers (as, for example, Selden, who states this very case) considered the formulist worthy of death as a murderer in intent; and upon this principle the trafficking with witches was punished in early times.

Witchcraft, however, by and by assumed greater statutory importance in England as elsewhere. Henry VIII.'s two acts were levelled against conjuration, witchcraft, false prophecies, and pulling down of crosses. Here the charge was still something beyond mere sorcery, and it was left for Elizabeth, in 1562, to direct a statute exclusively against that imaginary crime. At the same time, that princess extenuated her conduct in part, by limiting the penalty of the crime, when stripped of its customary accessories, to the pillory. The first transgression at least received no heavier punishment. The cases of Elizabeth's reign were chiefly cases of pretended possession, sometimes, however, involving capital charges against those said to have caused the possession. In one famous case, of which the main features were as ludicrous as the issue was deplorable, three poor persons—an old man named Samuel, with his wife and daughter—were tried at Huntingdon for having bewitched the children of a Mr Throgmorton. Joan Throgmorton, a girl of fifteen, and the eldest of the children, was the main witness for the prosecution. She related many scenes, in which the actors were herself and a number of spirits sent by Dame Samuel to torment her, and to throw her into fits. These spirits, she said, were on familiar terms with her, and were named Pluck, Hardname, Catch, Blue, and three Smacks, who were *cousins*. Among other things, she said that one of the Smacks professed himself an admirer of hers, and beat the rest for her sake, as in the following instance related by her. One day Smack appeared before her. 'Whence come you, Mr Smack?' she said to him. 'From fighting Pluck and the rest, with cowl-staves, in Dame Samuel's back-yard,' replied Smack; and soon thereafter, accordingly, Pluck and Blue walked in, the one with his head broken, and the

other limping. 'How do you manage to beat them?' said the young lady to the victorious Smack: 'you are little, and they are big.' 'Oh,' says Smack: 'I can take up any two of them, and my cousins beat the rest.' Of such stuff were these charges made. It would appear that they were either the offspring of insanity on the part of the youthful Throgmortons, or that, having begun the farce in sport or spite, the accusers found at length that they could not retreat without a disgraceful confession of imposture. In part, the conduct of the poor Samuels was affecting, and even high-minded. After lengthened worrying, the accusers got Dame Samuel indirectly to confess her guilt, by making her repeat a prescribed charm, which had the effect of at once bringing the children out of their fits. But the old man and the daughter steadily maintained their innocence. The unfortunate family were condemned on the 4th April 1593, and soon after executed.

When James I. ascended the English throne, he unfortunately conceived it to be his duty immediately to illuminate the southern on the subject of witchcraft. An act of the first year of his reign defines the crime with a degree of minuteness worthy of the adept from whose pen it undoubtedly proceeded. 'Any one that shall use, practise, or exercise any invocation of any evil or wicked spirit, or consult or convenant with, entertain or employ, feed or reward, any evil or wicked spirit, to or for any purpose; or take up any dead man, &c. &c. &c.; such offenders, duly and lawfully convicted and attainted, shall suffer death.' We have here witchcraft first distinctly made, of itself, a capital crime. Many years had not passed away after the passing of this statute, ere the delusion, which had heretofore committed but occasional and local mischief, became an epidemical frenzy, devastating every corner of England. Leaving out of sight single executions, we find such wholesale murders as the following in abundance on the Record. In 1612, twelve persons were condemned at once at Lancaster, and many more in 1618, when the whole kingdom rang with the fame of the 'Lancashire witches;' in 1622, six at York; in 1634, seventeen in Lancashire; in 1644, sixteen at Yarmouth; in 1645, fifteen at Chelmsford; and in 1645 and 1646, sixty persons perished in Suffolk, and nearly an equal number at the same time in Huntingdon. These are but a few selected cases. The poor creatures who usually composed these ill-fated bands are thus described by an able observer:—'An old woman with a wrinkled face, a furrowed brow, a hairy lip, a gobber tooth, a squint eye, a squeaking voice, or a scolding tongue, having a ragged coat on her back, a spindle in her hand, and a dog by her side—a wretched, infirm, and impotent creature, persecuted by all the neighbourhood because the farmer's cart had stuck in the gateway, or some idle boy had pretended to spit needles and pins for the sake of a holiday from school or work'—such were the poor unfortunates selected to undergo the last tests and tortures sanctioned by the laws, and which tests were of a nature so severe that no one would have dreamed of inflicting them on the vilest of murderers. They were administered by a class of wretches, who, with one Matthew Hopkins at their head, sprung up in England in the middle of the seventeenth century, and took the professional name of *witch-finders*. The practices of the monster Hopkins, who, with his assistants, moved from place to place in the regular and authorised pursuit of his trade, will give a full idea of the tests referred to, as well as of the horrible fruits of the witchcraft frenzy in general. From each town which he visited, Hopkins exacted the stated fee of twenty shillings, and in consideration thereof, he cleared the locality of all suspected persons, bringing them to confession and the stake in the following manner:—He stripped them naked, shaved them, and thrust pins into their bodies to discover the witch's mark; he wrapped them in sheets, with the great toes and thumbs tied together, and dragged them through ponds or rivers, when, if they sunk, it was held as a sign that the baptismal element did not

reject them, and they were cleared; but if they floated (as they usually would do for a time), they were then set down as guilty, and doomed: he kept them fasting and awake, and sometimes incessantly walking, for twenty-four or forty-eight hours, as an inducement to confession; and, in short, practised on the accused such abominable cruelties, that they were glad to escape from life by confession. If a witch could not shed tears at command (said the further items of this wretch's creed), or if she hesitated at a single word in repeating the Lord's Prayer, she was in league with the Evil One. The results of these and such-like tests were actually and universally admitted as evidence by the administrators of the law, who, acting upon them, condemned all such as had the amazing constancy to hold out against the tortures inflicted. Few gave the courts that trouble. Butler has described Hopkins in his 'Hudibras' as one

'Fully empowered to treat about  
Finding revolted witches out.  
And has he not within this year  
Hanged *three score* of them in *one* shire?  
Some only for *not* being drowned;  
And some for sitting above ground.'

After he had murdered hundreds, and pursued his trade for many years (from 1644 downwards), the tide of popular opinion finally turned against Hopkins, and he was subjected, by a party of indignant experimenters, to his own favourite test of swimming. It is said that he escaped with life, but from that time forth he was never heard of again.

The era of the Long Parliament was that perhaps which witnessed the greatest number of executions for witchcraft. *Three thousand persons* are said to have perished during the continuance of the sittings of that body, by legal executions, independently of summary deaths at the hands of the mob. Witch-executions, however, were continued with nearly equal frequency long afterwards. One noted case occurred in 1664, when the enlightened and just Sir Matthew Hale tried and condemned two women, Amy Dunny and Rose Callender, at Saint Edmondsbury, for bewitching children, and other similar offences. Some of the items of the charge may be mentioned. Being capriciously refused some herrings, which they desired to purchase, the two old women expressed themselves in impatient language, and a child of the herring-dealer soon afterwards fell ill—in consequence. A carter drove his wagon against the cottage of Amy Dunny, and drew from her some not unnatural oburgations; immediately after which, the vehicle of the man stuck fast in a gate, without its wheels being impeded by either of the posts, and the unfortunate Amy was credited with the accident. Such accusations formed the burden of the ditty, in addition to the bewitching of the children. These young accusers were produced in court, and on being touched by the old women, fell into fits. But on their eyes being covered, they were thrown into the same convulsions by other parties precisely in the same way. In the face of this palpable proof of imposture, and despite the general absurdity of the charges, Sir Matthew Hale committed Amy Dunny and Rose Callender to the tender mercies of the hangman. It is stated that the opinion of the learned Sir Thomas Browne, who was accidentally present, had great weight against the prisoners. He declared his belief that the children were truly bewitched, and supported the possibility of such possessions by long and learned arguments, theological and metaphysical. Yet Sir Matthew Hale was one of the wisest and best men of his time, and Sir Thomas Browne had written an able work in exposition of Popular Fallacies!

For several years subsequent to this (1664), trials and executions were yet far from unusual. Chief-Justices North and Holt, to their lasting credit, were the first individuals occupying the high places of the law, who had at once the good sense and the courage to set their faces against the continuance of this

## SUPERSTITIONS.

destructive delusion. In one case, by detecting a piece of gross imposture, Chief-Justice North threw into disrepute, once and for all, the trick of *pin-omiting*, one of the most striking and convincing practices of the possessed. A male sorcerer stood at the bar, and his supposed victim was in court, vomiting pins in profusion. These pins were straight, a circumstance which made the greater impression, as those commonly ejected in such cases were bent, engendering frequently the suspicion of their having been previously and purposely placed in the mouth. The chief-justice was led to suspect something in this case by certain movements of the bewitched woman; and by closely cross-questioning one of her own witnesses, he brought it fully out that the wretched creature placed pins in her stomach, and by a dexterous dropping of her head in her simulated fits, picked up the articles for each successive ejection. The man was found guiltless. The acquittal called forth such pointed benedictions on the judge from a very old woman present, that he was induced to ask the cause. 'Oh, my lord,' said she, 'twenty years ago they would have hanged me for a witch if they could, and now, but for your lordship, they would have murdered my innocent son.'

The detected imposture in this case saved the accused. It was under Holt's justiceship, however, that the first acquittal is supposed to have taken place, in *despite* of all evidence, and upon the fair ground of the general absurdity of such a charge. In the case of Mother Munnings, tried in 1694, the unfortunate pannel would assuredly have perished, had not Chief-Justice Holt summed up in a tone so decidedly adverse to the prosecution, that the verdict of Not Guilty was called forth from the jury. In about ten other trials before Holt, between the years 1694 and 1701, the result was the same, through the same influences. It must be remembered, however, that these were merely noted cases, in which the parties withstood all preliminary inducements to confession, and came to the bar with the plea of not guilty. About the same period—that is, during the latter years of the seventeenth century—summary executions were still common, in consequence of confessions extracted after the Hopkins fashion, yet too much in favour with the lower classes. The acquittals mentioned only prove that the regular ministers of the law were growing too enlightened to countenance such barbarities. Cases of possession, too, were latterly overlooked by the law, which would have brought the parties concerned to a speedy end in earlier days, even though they had done no injury to other people, and were simply unfortunate enough to have made compacts with the demon for the attainment of some purely personal advantages. For example, in 1689, there occurred the famous case of a youth named Richard Dugdale, who sacrificed himself to the devil, on condition of being made the *best dancer* in Lancashire. The dissenting clergy took this youth under their charge, and a committee of them fasted and prayed, publicly and almost incessantly, for a whole year, in order to expel the dancing demon. The idea of this impostor leaping for a twelvemonth, and playing fantastic tricks before these grave divines, is extremely ludicrous. But the divines played tricks not less fantastic. They became so contemptuously intimate with the demon, as to mock him on account of saltatory deficiencies. A portion of their addresses to him on this score has been preserved, but of too ridiculous a nature for quotation in these pages. If anything else than a mere impostor, it is probable that Dugdale was affected with St Vitus's Dance; and this is the more likely, as a regular physician brought his dancing to a close after all. But the divines took care to claim for themselves the merit of the cure.

After the time of Holt, the ministers of the law went a step farther in their course of improvement, and spared the accused in spite of condemnatory verdicts. In 1711, Chief-Justice Powell presided at a trial where an old woman was pronounced guilty. The judge, who had sneered openly at the whole proceedings, asked the

jury if they found the woman 'guilty upon the indictment of conversing with the devil in the shape of a cat?' The reply was, 'We do find her guilty of that;' but the question of the judge produced its intended effect in casting ridicule on the whole charge, and the woman was pardoned. An able writer in the Foreign Quarterly Review remarks, after noticing this case, 'yet, frightful to think, after all this, in 1716, Mrs Hicks, and her daughter, aged *nine*, were hanged at Huntingdon for selling their souls to the devil, and raising a storm by pulling off their stockings, and making a lather of soap! With this crowning atrocity, the catalogue of murders in England closes.' And a long catalogue, and a black catalogue it was. 'Barrington, in his observations on the statute of Henry VI., does not hesitate to estimate the numbers of those put to death in England, on this charge, at THIRTY THOUSAND!'

We have now glanced at the chief features in the history of witchcraft in England, from the enactment of the penal statutes against it. These statutes were not finally abolished till the middle of the eighteenth century, and unhappy consequences followed, in various instances, from their being left unrepealed. Though among the enlightened classes the belief in witchcraft no longer existed, the populace, in town and country, still held by the superstitions of their forefathers, and having the countenance of the statute-book, persecuted the unfortunate beings whose position and circumstances laid them open to the suspicion of sorcery. The ban of public opinion told severely enough upon the comforts of such poor creatures, but the rabble occasionally carried their cruel and ignorant oppressions to a greater length. On the 30th of July 1751, an aged pauper named Osborne, and his wife, were seized by a mob in Staffordshire, dragged through pools, and otherwise so vilely misused, that the woman died under the hands of her assailants. The attention of the law, and the indignation of the humane, were aroused. One man, who had taken a prominent share in the brutal outrage, was condemned on trial, and executed. Immediately afterwards, the penal statutes against witchcraft were abrogated by the legislature, and the remembrance of them only remains, as a wonder and warning to the posterity of those who practised and suffered from them, as well as to mankind at large.

It must not be imagined, we may observe in conclusion, that the present generation has no need of such a warning, or is relieved by its increased enlightenment from all chance of falling into similar errors. The nineteenth century has witnessed such impostors as Johanna Southcote, Matthews, Thom, Mormon, and others, and has seen a degree of enthusiastic and unhesitating credence given to their pretensions by many persons moving in a most respectable rank in society, which shows that the credulous spirit that created and supported witchcraft is not by any means extinguished. It is indeed a spirit only to be fully eradicated by such a universality of education and manly intelligence as can scarcely be expected to exist, excepting after the lapse of long-coming centuries of improvement. The subject which has been treated of here has therefore a moral. In brief words, the world may learn from it the peril of encouraging the idea of the possibility of direct spiritual influences and communications in these latter days—a thing discountenanced alike by the lights of reason and Scripture.

### SPECTRAL ILLUSIONS.

The subject of spectral illusions, or, to use the common phraseology, apparitions or spectres, is now, in the estimation of scientific and properly-informed men, one of the simplest and most intelligible to which the mind can be directed; while, to the ignorant, it still appears full of doubt and mystery. An apparition, spectre, ghost, or whatever it may be called, is vulgarly supposed to be a supernatural appearance—a thing occurring out of the common order of nature. No particular time or place is assigned for the appearance; but we may observe that the time is usually evening or night, and the place soli-

tary, or apart from the busy haunts of man. According to old theories on the subject, the person who declared that he had seen such an appearance was either set down as the fabricator of an untruth, or his story was fondly believed, and in the latter case the supernatural incident was added to the mass of credible history. We shall now endeavour to set this conflict of testimony and opinion to rights. In all cases, it is quite possible for the declarant to speak the truth as respects what he saw, or thought he saw, and yet that no real apparition may have occurred. The whole affair, as we shall explain, is simply a mental delusion, caused by some species of disease in the organs which affect the vision.

Mental and bodily disorder, organic or functional, is now allowed by physicians to be the basis of all kinds of spectral illusion. Organic disorder of the body is that condition in which one or more organs are altered in structure by disease. Disease of the brain, which involves organic mental disorder, is properly disease of the body; but enduring lunacy or fatuity, existing (if they can do so) without disease in the structure of the brain, may also be called organic disorder of the mind. These explanations will show what is meant by that epithet, as applied either to affections of the mind or body. Functional disorder, again, of the mind or body, is that condition of things where the healthy action of the organ or organs, in part or whole, is impeded, without the existence of any disease of structure. It may be said that violent excitement of the imagination or passions constitutes functional mental disorder: 'anger is a temporary madness,' said the Romans wisely. As for functional bodily disorder, temporary affections of the digestive organs may be pointed to as common cases of such a species of physical derangement. All these disorders, and kinds of disorders, may appear in a complicated form, and, what is of most importance to our present argument, the *nervous system*, on which depends the action of the *senses*, the power of *volition*, and the operation of all the involuntary functions (such as the circulative and digestive functions), is, and must necessarily be, involved more or less deeply in all cases of constitutional disorder, organic or functional. These powers of the nerves, which form the sole medium by which mind and body act and react on each other, give us a clue to the comprehension of those strange phenomena called spectral illusions, which depend on a combination of mental and physical impressions.

Organic mental disorder generates spectral illusions. Almost every lunatic tells you that he sees them, and with truth; they are seemingly present to his diseased perceptions. The same cause, simply insanity, partial or otherwise, and existing either with or without structural brain disease, has been, we truly believe, at the foundation of many more apparition cases than any other cause. By far the greatest number of such cases ever put on record have been connected with fanaticism in religious matters; and can there be a doubt that the majority of the poor creatures, men and women, who habitually subjected themselves, in the early centuries of the church, to macerations and lacerations, and saw signs and visions, were simply persons of partially deranged intellect? St Theresa, who lay entranced for whole days, and who, in the fervour of devotion, imagined that she was frequently addressed by the voice of God, and that our Saviour, St Peter, and St Paul, would often in person visit her solitude, is an example of this order of monomaniacs. That this individual, and others like her, should have been perfectly sensible on all other points, is a phenomenon in the pathology of mind too common to cause any wonder. We would ascribe, we repeat, a large class of apparition cases, including these devotional ones, to simple mental derangement. The eye in such instances may take in a correct *impression* of external objects, but this is not all that is wanting. A correct *perception by the mind* is essential to healthy and natural vision, and this perception the deranged intellect cannot effect. A three-footed stool may then become a kneeling angel. We would therefore have such persons regarded not in the uncharitable light of

impostors, but of poor creatures who mistook natural hallucinations for supernatural.

Undoubtedly, however, many of those cases of spectral illusions which have made the deepest impression on mankind, have not arisen from organic mental disease on the part of the sight-seers. The lunatic is apt to betray his condition, and, that once recognised, his visions become of no weight. We have then to turn to other causes of spectre-seeing; and first, let us notice the mode of operation, and effects of certain *functional* disorders of the system, operating on the visual perceptions through the nerves. A bodily disorder, which ought in itself to afford a solution of all apparitions, is that called *delirium tremens*. This is most commonly induced, in otherwise healthy subjects, by continued dissipation. So long (say medical authorities) as the drinker can take food, he is comparatively secure against the disease, but when his stomach rejects common nourishment, and he persists in taking stimulants, the effects are for the most part speedily visible, at least in peculiarly nervous constitutions. The first symptom is commonly a slight impairment of the healthy powers of the senses of hearing and seeing. A ringing in the ears probably takes place; then any common noise, such as the rattle of a cart on the street, assumes to the hearing a particular sound, and arranges itself into a certain tune perhaps, or certain words, which haunt the sufferer, and are by and by rung into his ears on the recurrence of *every* noise. The proverb, 'as the fool thinks, so the bell tinkles,' becomes very applicable in his case. His sense of seeing in the meanwhile begins to show equal disorder; figures float before him perpetually when his eyes are closed at night. By day, also, objects seem to move before him that are really stationary. The senses of touch, taste, and smell, are also involved in confusion.

In this manner the disturbance of the senses goes on, increasing always with the disorder of the alimentary function, until the unhappy drinker is at last visited, most probably in the twilight, by visionary figures, distinct in outline as living beings, and which seem to speak to him with the voice of life. At first he mistakes them for realities, but soon discovering his error, is thrown into the deepest alarm. If he has the courage to approach and examine any one of the illusory figures, he probably finds that some fold of drapery, or some shadow, has been the object converted by his diseased sense into the apparition, and he may also find that the voice was but some simple household sound converted by his disordered ear into strange speech; for the senses, at least in the milder cases of this sort, rather *convert* than *create*, though the metamorphosed may differ widely from the real substance. The visitations and sufferings of the party may go on increasing, till he takes courage to speak to the physician, who by great care restores his alimentary organs to a state of health, and in consequence, the visions slowly leave him. If, however, remedies are not applied in time, the party will probably sink under the influence of his disorder. The spectral figures and voices, being solely the creation of his own fancy, will seem to do or say anything that may be uppermost in that fancy at the moment, and will encourage him to self-murder by every possible argument—all emanating of course from his own brain. The whole consists merely of his *own fancies bodied forth to him visibly and audibly*. His own poor head is the seat of all; there is nothing apart from him—nothing but vacancy.

Dr Alderson, a respectable physician, mentions his being called to a keeper of a public-house, who was in a state of great terror, and who described himself as having been haunted for some time with spectres. He had first noticed something to be wrong with him on being laughed at by a little girl for desiring her to lift some oyster shells from the floor. He himself stooped, but found none. Soon after, in the twilight, he saw a soldier enter the house, and not liking his manner, desired him to go away; but receiving no answer, he sprang forward to seize the intruder, and to his horror

## SUPERSTITIONS.

found the shape to be but a phantom! The visitations increased by night and by day, till he could not distinguish real customers from imaginary ones, so definite and distinct were the latter in outline. Sometimes they took the forms of living friends, and sometimes of people long dead. Dr Alderson resorted to a course of treatment which restored the strength of the digestive organs, and gradually banished the spectres. At the close of the account, it is said that the man emphatically expressed himself to have now received 'a perfect conviction of the nature of ghosts.'

Many additional cases from Hibbert, Abercromby, and other writers, might be quoted, in which the visual impressions and perceptions were in a similar way affected by the influence of digestive derangement. But as no doubt can rationally exist on the point, from the comparative commonness of the disease, no more proof need be brought forward. However, the inference naturally deducible from these facts is too important to be overlooked. Here we find, by unquestionable medical evidence, that a man walking about in apparent bodily health, and mentally sane, may nevertheless be subject to most distinct visitations of spectral figures, some of them in the semblance of *dead persons*. We find this, we repeat, to be within the range of natural phenomena. Now, is it not more likely, in those cases where wonderful apparitions are reported to have been seen, that the whole was referable to such natural causes, than that the grave gave up its dead, or that the laws of the universe were specially broken in upon in any other way! Even with only one such admitted source of spectral illusions as the malady alluded to, we should certainly err in passing it by to seek for explanations in supernatural quarters. But in reality we have *many* causes or sources of them, and to these we shall now look, in continuation of our argument.

Among the other varieties of bodily ailments affecting either structure or function, which have been found to produce spectral illusions—fevers, inflammatory affections, epileptic attacks, hysteria, and disorders of the nerves generally, are the more prominent. As regards fevers and inflammatory affections, particularly those of the brain, it is well known to almost every mother or member of a large family, that scarcely any severe case can occur without illusions of the sight to a greater or less extent. In hysteric and epileptic cases, also, where fits or partial trances occur, the same phenomena are frequently observed. But we shall not enlarge on the effects produced by the influence of severe and obviously-existing maladies, as it is in those cases only where the spectre-seer has exhibited *apparent* sanity of mind and body, that special wonder has been excited. It is so far of great importance, however, to notice that these diseases do produce the illusions, as in most cases it will be found on inquiry that the party subject to them, however sound to appearance at the time, *afterwards* displayed some of these complaints in full force; and we may then rationally explain the whole matter by supposing the seeds of the ailments to have early existed in a latent state. A German lady, of excellent talents and high character, published an account some years back of successive visions with which she had been honoured, as she believed, by Divine favour. Dr Crichton, however, author of an able work on insanity, found that the lady was always affected with the *aura epileptica* during the prevalence of the illusions; or, in other words, that she was labouring under slight attacks of epilepsy. Thus simply was explained a series of phenomena which, from the high character for veracity of the subject of them, astonished a great part of Germany. Another case, where functional bodily disorder of a different and very simple kind was present in an unrecognisable state, and produced extraordinary illusions, was the famous one of Nicolai, the Berlin bookseller. This individual, when in a perfectly fit state to attend to his ordinary business, was suddenly visited one day, when casually excited by some annoying circumstance, by the figure of a person long dead. He asked his wife, who was pre-

sent, if she saw it; she did not. The bookseller was at first much alarmed, but being a man of sense and intelligence, he soon became convinced of the illusory, yet natural character of the spectra, which subsequently, for a period of two whole years, appeared to him in great numbers, and with daily frequency. 'I generally saw,' says he, 'human forms of both sexes, but they took not the smallest notice of each other, moving as in a market-place, where all are eager to press through the crowd; at times, however, they seemed to be transacting business with one another. I also saw several times people on horseback, dogs, and birds. All these phantasms appeared to me in their natural size, and as distinct as if alive; none of the figures appeared particularly terrible, comical, or disgusting, most of them being of an indifferent shape, and some presenting a pleasing aspect. The longer these phantoms continued to visit me, the more frequently did they return.' They also spoke to him repeatedly.

These phantasms lasted, as we have said, two years. The issue is peculiarly worthy of note. Nicolai had in former years fallen into the habit of periodical blood-letting by leeches, but had ventured to stop the practice previous to the accession of the phantasms, and during their prevalence he had only been advised to attend to the state of his digestive organs. After they had endured for the time mentioned, it was thought fit to renew the blood-letting. At eleven in the morning, while the room was crowded with the spectral figures, the leeches were applied. As the bleeding slowly proceeded, the figures grew dimmer and dimmer, and finally, by eight o'clock in the evening, they had all melted into thin air, never to re-appear! This most remarkable case, the first in which any individual dared calmly to come forward and avow such an affection, at the risk of incurring the charge of insanity, was founded, we thus see, simply on a plethoric or surcharged state of the blood-vessels. Nicolai deserves great credit for the philosophic composure with which he recorded the phenomena presented to him; but his statement, which has often been republished in this country, seems defective in some points, and, from the interest of the subject, we may be pardoned for presuming to notice these. Generally speaking, he represents his spectral visitants as things which came and went, and assumed various shapes, and appeared in certain numbers, *uninfluenced* directly by himself. The total dependance which they had upon his own fancy of the moment, is not put clearly before us, though, by the truthful accuracy of his narrative, he unconsciously makes that fact apparent every instant. The surcharged state of the vessels was the fundamental cause of the phantasms, but his own passing fancies moulded them for the passing moment into shape, regulated their numbers, and gave them words. How could it be otherwise! The whole panorama was exhibited on his own retina, and the working brain behind was the manager and scene-shifter of the show.

*Second-sight*, taking the word in its common acceptation of supernatural sight-seeing, is one of the varieties of spectral illusion. Certain mental functions becoming diseased, the sense of sight is imposed upon by the appearance of things which are purely imaginary, but nevertheless supposed to be prophetic of future events. Idleness, solitude, insufficient diet, and an imagination led astray by ruminating too intensely on the causes of human weal and wo, may be assigned as the prevailing causes of the disease. The Lowland Scotch used occasionally to see *wraiths*, or spectral appearances of persons who were soon to quit this mortal scene; the Irish were also accustomed to the spectacle of *feiches*; and the Highlanders had their *second-sight*—the whole, be it observed, being but a variety of the same mental disease and delusion.

Second-sight, however, has formed the subject of a more regular profession than any other species of spectral frenzy. There were persons who, possessing from infancy a defective mental constitution, or having a taste for imposture, gave themselves out as habitual

sight-seers, and were revered accordingly by their unsophisticated neighbours. According to the credulous accounts of second-sight, the power of the seer is a natural endowment, and cannot be acquired by communication, or in any other way. It is usually talked of by its possessors as a painful and troublesome gift, and one which they would gladly be rid of if they could. Its vaticinations relate only to things to come, and not to past events. Young and old may alike possess the second-sight, and it is common also to men and women. The visions are sometimes predicative of good, and sometimes of evil: occasionally, the vision simply gives indifferent tidings.

These are a few of the most common peculiarities attendant on this faculty. There are likewise numberless rules affecting its exercise, and the interpretation of its visions. If a vision occur by day, for example, the accomplishment of what it is supposed to predict will be speedy; if by night, less so. An exact proportion, indeed, is maintained in this respect—the morning vision being sooner fulfilled than that of noon; the latter more quickly than that of the afternoon; and so on. If the seer beholds a figure in a shroud, it is considered a sure sign of death to the party represented by the figure; and according to the extent to which the shroud covers the body, the end will be quicker or slower. If a woman be seen at a man's left hand, it is a presage that she will be his wife, and this will be the case (say the true believers) though even both should then be married. If more than one woman be seen standing at a man's left hand, they will be married to him in rotation, as they stand nearer or farther from his arm. A seer often announces that such and such a guest will arrive at a certain hour, and though a hundred miles away, the guest, it is said, will appear at the stated time. If a seer observe a vision of trees and crops in some spot or another, though perfectly barren and bare at the moment, wood and grain will, it is believed, there be seen in due time. A visionary house is beheld by the gifted eye in a place where stone and lime were never laid, or expected to be laid; yet there will the real house forthwith be seen. To see a seat as if vacant when one is sitting in it, is a presage of the party's death. The seer may behold crowds of people, or single individuals, and very frequently he meets imaginary funeral parties, and determines the coming decease by the apparent mourners.

These rules of vaticination are said to be unvarying. No ordinary person sees the vision while it is present to the seer, but the same vision often appears to two or more of the gifted, either while they are together or apart. The Highlanders believe that children and the lower animals, such as cows and horses, behold the appearances while they are before the seer. This is made plain, they say, in the case of the animals, by the trembling which seizes them at the moment; and frequently the children will cry, and if asked the reason, will tell what unusual thing they behold or have beheld. It is almost needless to say that the stories told to prove the truth of these notions rest on no sure foundation, and that, at the best, the prophecies of the sight-seer only come to pass by chance.

*Atmospheric Illusions.*—Spectral or illusory appearances also take place from the power of refraction in the atmosphere. In certain conditions of the atmosphere, things at a distance, and really out of sight, as on the opposite side of a hill from the spectator, are represented in mid-air; but there is nothing supernatural in this—the whole is the effect of a simple cause. The following is an example of atmospheric illusion:—A gentleman and his servant, in the year 1744, beheld a troop of cavalry riding and performing various military evolutions on the side of Souter (or Soutra) Hill, in a spot so precipitous, as to render it absolutely impossible for man or beast to maintain a footing. The servant had in the previous year observed a single horseman hunting in nearly the same place, and had then come to the conclusion that the sight was illusory, it being

impossible for a rider to cross a perpendicular precipice at speed. The troop of cavalry, therefore, was at once set down as an atmospheric deception, and numbers of persons of the district came to look on the extraordinary scene, which continued visible till nightfall. An explanation of the circumstance was afforded by the rebellion of the following year. Some party of rebels were most probably exercising in secret, in a spot where the evening sun so caught their figures as to reflect them on the acclivity of Souter Hill. The legend of the spectre of the Brocken in Germany, in like manner arises from the fact of the ground being favourable to the reflection of a visitor's figure against the evening sky. Our ancestors were occasionally alarmed with visions of armies fighting in the air, and similar illusions; had they been acquainted with the laws of atmospheric refraction, all would have appeared simple natural phenomena, having no relation to any future event, good or evil. (See *OPTICS*, Vol. I.)

#### Dreams.

It has now been seen that there are various modes in which the system may be so disturbed as to produce spectral illusions, and that, in the majority of these cases, the parties subject to them might seem to be not only of sound mind, but in perfect bodily health. Another mode of explaining cases of this description may now be pointed out. Many of the apparitions which have been vouched for by those subjected to them, have certainly been neither more nor less than *vivid dreams*. A dream is a slight and ill-arranged action of the thinking faculties during a state of partial sleep; in other words, when we dream we are only thinking in a partially-wakened state. The dream or the thought is in all cases but a momentary impression, perfectly natural in its operation; the state of mind which causes it being produced by temporary functional derangement; the stomach is usually less or more out of order. No dreams take place during sound sleep. In the greater number of instances, the half-awakened mind embarrasses itself with shreds of recollections of things formerly seen or thought of, and dressing these up in a new and fantastic form, a kind of drama is performed, having the semblance of reality. A servant-girl living in a family where there were some phrenological busts, and among others, a conspicuous one of Curran, awoke her bed companion one morning with the alarming information that the ghost of Curran stood at the foot of the bed dressed in a sailor's jacket, and having on his pale face the unwonted and unbust-like ornament of an immense pair of black whiskers. The other servant could see nothing, though the apparition seemed to her companion to remain visible for some minutes. On the tale being told, a pretty strong light was thrown on the matter. The master of the house had a yacht, and its sailors at that period were frequently about the premises. Going to bed much fatigued, and having her dreaming thoughts divided between her household duties and some gay whiskered beau of the yacht, the girl's fancy had dressed up Curran's bust, an object most familiar to her retina, in the way mentioned, giving him the sailor's person and whiskers as a fitting appendage. Had the object called up to the eye in this case, instead of being a bust of Curran, chanced to be a portrait of some wicked ancestor or ancestress of the family, as might easily have occurred from the greater comparative impression made on the mind by portraits of that cast, then should we have had a splendid instance of the preternatural appearance of a spirit stung by remorse, and haunting restlessly the scene of its mortal guilt. The girl, without imposture, might have conscientiously reiterated her conviction of the reality of the vision, and the possession of a haunted chamber would have most certainly been assigned to the mansion, inspiring such terror, that renewals of the illusion might really have taken place in consequence. Where the whole affair is not a fiction in such haunted-chamber cases, some solution of this kind may be with certainty applied. The prac-

## SUPERSTITIONS.

tice of believing that dreams are indicative or symbolic of coming events, is one of the weakest of our popular superstitions, and is now very properly ridiculed by every rational mind.

### MISCELLANEOUS SUPERSTITIONS.

During the seventeenth century, the belief in witchcraft, fairies, apparitions, charms, and every other species of supernatural agency, was universal in Britain, both among high and low, and clergy as well as laity. So ill instructed were the people in the art of tracing events to simple natural causes, that there appears to have been a continual liability to ascribe occurrences to the direct influence of good or evil spirits, but particularly to the devil. 'Give me leave,' says Walker in his 'History of Independency,' 'here to relate a passage, which I received from a person of quality—namely, It was believed, and that not without good cause, that Cromwell, the same morning that he defeated the king's army at Worcester fight, had conference personally with the devil, with whom he made a contract, that to have his will then, and in all things else, for seven years after that time (being the 3d of September 1651), he should, at the expiration of the said years, have him at his command, to do at his pleasure, both with his soul and body. Now if any one will please to reckon from the 3d of September 1651 till the 3d of September 1658, he shall find it to a day just seven years, and no more, at the end whereof he died; but with such extremity of tempestuous weather, that was by all men judged to be prodigious.' Such is a specimen of the egregious fallacies which passed for sound argument among our ancestors.

In Scotland, where religion assumed the garb of gloom and fanaticism, a belief in the personal appearance of devils was universal in the seventeenth century, and continued among the vulgar till within the last fifty years. The narrations of Satan's mean pranks, in assailing ministers, waylaying travellers, and disturbing families while at worship, would fill a large volume. In the Rev. Mr Robert Law's 'Memorials of Memorable Things, from 1638 to 1684'—[edited by C. Kirkpatrick Sharpe, from the manuscript. Edinburgh: 1818]—we find the following entry:—

'October 1670.—There was a devil that troubled a house in Keppoch, within a mile of Glasgow, for the matter of eight days' tyme (but disappeared again), in casting pots, and dropping stones from the roof, yet not hurting any, like that which appeared in the west, in a weaver's house, a good man, about fourteen yeirs agoe, which did the lyke, and spoke to them audibly.' The tricks of the devil, here referred to, as having taken place in a weaver's house in the west, about the year 1656, and which were implicitly believed by the most learned clergy of the time, are related at great length by Mr George Sinclair, professor of philosophy in the College of Glasgow, in his work, 'Satan's Invisible World Discovered.' The alleged events occurred at Glenluce in Wigtonshire, and would be too contemptible for quotation, if it were not desirable to show what paltry tricks were played off, and believed to be supernatural in those days. The family of the weaver being vexed with noises and appearances, send for the neighbouring clergyman to allay the devil, betwixt whom and the worthy man a dialogue takes place, from which we extract a few passages:—'The minister returning back a little, and standing upon the floor, the devil said, "I knew not these Scriptures till my father taught me them." Then the minister conjured him to tell whence he was. The foul fiend replied, "That he was an evil spirit, come from the bottomless pit of hell to vex this house, and that Satan was his father." And presently there appeared a naked hand, and an arm from the elbow down, beating upon the floor till the house did shake again; and also he uttered a most fearful and loud cry, saying, "Come up, my father—come up. I will send my father among you: see, there he is behind your backs!" Then the minister said, "I saw, indeed, a hand and an arm, when the stroke was given,

and heard." The devil said to him, "Saw you that? It was not my hand; it was my father's: my hand is more black in the loof (palm.) Would you see me," says the foul thief, "put out the candle, and I shall come butt the house (into the outer room) among you like fireballs," &c. The visit of the minister was unavailing. 'About this time the devil began with new assaults; and taking the ready meat which was in the house, did sometimes hide it in holes by the door-posts, and at other times hid it under the beds, and sometimes among the bed-clothes and under the linens, and at last did carry it quite away, till nothing was left there save bread and water. The goodwife, one morning making porridge for the children's breakfast, had the wooden plate, wherein the meal lay, snatched from her quickly. "Well," says she, "let me have my plate again." Whereupon it came flying at her, without any skaithe done.' Any further extract from this ridiculous, though at one time universally believed narrative, would be unnecessary. A modern police-officer would have effectually relieved 'the afflicted family,' by instantly discovering the performer of the tricks, and taking him into custody.

Besides the belief in aerial and terrestrial spirits, our credulous ancestors put faith in all kinds of romancing stories of river and sea demons. The more prevalent of these superstitious notions was a belief in mermaids and mermen, a class of creatures who lived in the sea, and had bodies half-human half-fish. Mermaids appear to have been much more common than mermen. The mermaid, we are told, possessed the body, from the middle upwards, of a beautiful female, with a head flowing with long yellow hair, which she incessantly combed with one hand, while she held a small mirror with the other. This female monster of the deep is described as having been a constant schemer of destruction to confiding navigators, or those who haunted unfrequented parts of the sea-shores.

Another of the vulgar superstitions of our ancestors was a belief, common to nations of Germanic origin, that the corpse of a murdered person would bleed on being touched by the person who was guilty of the murder. Strange to say, this species of evidence of guilt was at one time admitted in the Scottish criminal courts. The following incredible instance was communicated to Sir Walter Scott, and is given in his 'Minstrelsy of the Scottish Border' (vol. ii. p. 54). 'Two young men, going a-fishing in the river Yarrow, fell out, and so high ran the quarrel, that the one, in a passion, stabbed the other to the heart. Astonished at the rash act, he hesitated whether to fly, give himself up to justice, or conceal the crime; and in the end fixed on the latter expedient, burying the body of his friend very deep in the sands. As the meeting had been accidental, he was never suspected, although a visible change was observed in his behaviour, from gaiety to a settled melancholy. Time passed on for the space of fifty years, when a smith, fishing near the same place, discovered an uncommon and curious bone, which he put in his pocket, and afterwards showed to some people in his smithy. The murderer being present, now an old white-headed man, leaning on his staff, desired a sight of the little bone; but how horrible was the issue!—no sooner had he touched it, than it streamed with purple blood. Being told where it was found, he confessed the crime, was condemned, but was prevented by death from suffering the punishment due to his crime.' We need only add, that no evidence is given of the truth of this improbable tale, and it is, therefore, utterly unworthy of belief.

Ignorance has often been justly termed the mother of superstition; wherever mankind are most ignorant, or least accustomed to trace events to their natural and proximate causes, there do all kinds of superstitious notions luxuriantly flourish. When the mind once allows that matters of ordinary occurrence may take place by the interference of invisible agents, such as spirits, apparitions, devils, and so forth, there is obviously no limit to the actions they are supposed to

perform. Hence the number of events believed to be ominous of evil in unenlightened society. The appearance of two or three magpies, hares crossing one's path, the spilling of salt at table, the cracking of furniture, the howling of dogs, putting on the left shoe first, the ticking noise of an insect (the death-watch) in rotten wood, and a hundred other trifling occurrences, are imagined to be harbingers of evil.

## THE ROSICRUCIANS.

In the early part of the seventeenth century, while the most degrading superstitions prevailed in Europe, there sprung up a sect in Germany under the name of Rosicrucians, who taught the wildest fancies. Though as far astray in their notions as the Demonologists and witch believers, their creed was more graceful. They taught that the elements swarmed not with hideous, foul, and revengeful spirits, but with beautiful creatures, more ready to do man service than to inflict injury. They taught that the earth was inhabited by Gnomes, the air by Sylphs, the fire by Salamanders, and the water by Nymphs or Undines; and that man, by his communication with them, might learn the secrets of nature, and discover all those things which had puzzled philosophers for ages—Perpetual Motion, the Elixir of Life, the Philosopher's Stone, and the Essence of Invisibility.

The Rosicrucians derived their name from Christian Rosencreütz, their founder, who died in 1484. This man was a professor of alchemy, or the pretended art of transmuting the baser metals into gold, which was spoken of as the discovery of the Philosopher's Stone. Being therefore a visionary, it was natural for such a person to found a religious sect, with doctrines of a fantastic kind. He is said to have bound his disciples, by solemn oaths, to keep his doctrine secret for one hundred and twenty years after his burial. Certain it is, they were never heard of under this name until the year 1604, when they first began to excite attention in Germany. Michael Meyer, an alchemist, and a physician of repute, was the first person of any note who lent the authority of his name to the promulgation of their tenets. He published at Cologne, in 1615, a work entitled 'Themis Aurea, hoc est de legibus Fraternalitatis Rosæ Crucis,' which purported to contain all the laws and ordinances of the brotherhood.

The sect may be said to have now fairly commenced operations, the members calling themselves brethren of the Rosy Cross, by a play on the name of the founder. From the work of Meyer above cited, it appeared that, by perfect temperance and chastity, the brethren expected to hold converse with the elemental spirits; that they could render themselves invisible; draw gold and jewels from the bowels of the earth by incantation; be subject neither to disease nor death; and subsist without eating or drinking! They also laid claim to the power of foretelling all events, and of curing all diseases; and asserted that they possessed all wisdom and knowledge in a supreme degree. But beyond the confines of Cologne, Frankfort, and some other German cities, the name of the sect was not much known until the year 1623, when some of the brethren suddenly made their appearance in Paris, and frightened the good people of that capital from their propriety. On the 3d of March in that year, the following placard was stuck upon the walls, but how it came there nobody could tell:—

'We, the deputies of the principal college of the Brethren of the Rosy Cross, have taken up our abode, visible and invisible, in this city, by the grace of the Most High, towards whom are turned the hearts of the just. We show and teach without any books or symbols whatever, and we speak all sorts of languages in the countries wherein we deign to dwell, to draw mankind, our fellows, from error, and to save them from death.'

Viewed as impostors, the Rosicrucians were driven for a while from France, and their *philosophy*—for such it was called—found believers and preachers in Holland, England, and Italy. The most celebrated in the

former country was Peter Mormius, an alchemist. In England, the high priest of the doctrine was one Dr Fludd, or, as he loved to call himself, Robertus à Fluctibus. This man had very strange notions upon medicine, which he had studied chiefly in the pages of Paracelsus. He warmly embraced the Rosicrucian creed; boasted of his intercourse with the elementary spirits, with whom he had conversations far surpassing those of Dr Dee with the angels; asserted that he could live without food for a couple of centuries, or until it pleased him to die; and that he could render himself invisible, and turn all metals into gold. But the most illustrious Rosicrucian was Joseph Francis Boni, an Italian, who wrote a treatise on the doctrines of the sect; and on this treatise the Abbé de Reillers founded his cabalistic romance, 'The Count de Gabbolis,' which is now the best authority on the subject. According to this work, the leading doctrine of the Rosicrucians is, that the whole of creation—earth, air, water, fire—is occupied by spirits. 'The air is filled with an innumerable multitude of beings in human shape—proud and majestic in their appearance, but very mild in reality. They are great lovers of science, subtle, fond of rendering service to the wise, but great enemies of the foolish and the ignorant. . . . The seas and the rivers are inhabited in like manner. The ancient sages named these people the Undines, or the Nymphs. The males are few among them, but the females are in great number. Their beauty is extreme, and the daughters of man cannot be compared to them. The earth is filled almost to the centre with Gnomes—people smaller in stature, who guard the treasures of the mines, and keep watch over precious stones. These are very ingenious, very friendly to man, and easy to command. They furnish the children of philosophy (the Rosicrucians) with all the money they require, and think themselves sufficiently rewarded by our friendship. The Gnomides, their females, are small, but very beautiful and agreeable, and their dress is very curious. As regards the Salamanders, inhabitants of the fire, they also render service to the children of philosophy, but do not seek their company so eagerly as the others; and their wives and daughters are very rarely seen by mortal eyes. . . . They are by far the most beautiful of the elementary spirits, being compounded of the most subtle and beautiful of all the elements. By becoming a member of our fraternity, you will be enabled to see and converse with all these glorious multitudes; you will see their mode of life, their manners, and make acquaintance with their admirable laws.' These beings are mortal; but 'a Nymph or a Sylphid becomes immortal, and has a soul like man, if she can inspire one of us with love towards her; thus a Sylph or a Gnome ceases to be mortal if one of the daughters of man will consent to marry him.'

The Rosicrucians taught that by the practice of virtue alone, man could hope to hold communion with the spirits of the elements: the attendant spirit in Comus teaches the same doctrine:—

'Mortals, that would follow me,  
Love Virtue; she alone is free:  
She can teach ye how to climb,  
Higher than the spher's chime;  
Or if Virtue feeble were,  
Heaven itself would stoop to her.'

There being a degree of elegance and poetry in these wild reveries of the Rosicrucians, they are believed to have furnished a basis for the Sylphs, Sylphids, and Ariels of Shakspeare, Milton, and other English poets. In recent times, literature is not slightly indebted to the superstitious conceptions of the Rosicrucians. It will suffice to mention the charming story of 'Undine,' by the Baron de la Motte Fouqué; 'Zanoni,' by Sir E. L. Bulwer; and, more recently, the popular poem of the 'Salamandrine,' by Dr Charles Mackay, to show how rich are the materials afforded to poets and romance writers by the fancies of this curious, and now all but forgotten sect.

## KEY TO THE CALENDAR.

### JANUARY.

JANUARY and FEBRUARY are said to have been added to the list of months by the second Roman king, Numa Pompilius, in the year before Christ 672. The name of the former month is unquestionably from Janus, the god of the year in the Roman mythology, to whom the first day was sacred, and in whose honour it was celebrated with riotous feasting and givings of presents. We learn from Ovid's *Fasti*, that a Roman workman did not spend the Kalends or 1st of January entirely in debauchery: he wrought a little at his trade, for the sake of good-luck throughout the year.

1. *Circumcision*.—A festival of the Romish Church, from about the year 487, and of the Church of England since 1550, in honour of the circumcision of Christ. The banks and public offices are shut on this day. As the first day of the year, it is celebrated throughout the modern Christian world with festive rejoicings, too often approaching or exceeding the bounds of propriety. In England, till a period not very remote, it was customary to usher in the year by drinking spiced liquor from the *Wassail Bowl*, so called from the Anglo-Saxon *Waes-hael* (Be healthy), the toast used on the occasion. The custom without the name still exists in Scotland. It was also customary on this day to give and receive gifts, originally with the superstitious design of securing good fortune for the year, and afterwards for affection and to promote good neighbourhood. Even the kings of England accepted presents from their courtiers on this morning. The 1st of January, under the name of *Le Jour de l'an*, continues in France to be distinguished by a universal system of present-giving, in which the royal family partakes. It has been calculated that sweetmeats to the value of £20,000 are sold in Paris on this day.

6. The *Epiphany*, a festival in honour of the manifestation of the infant Jesus to the three wise men of the East, who came to worship him. It began to be celebrated in 813. This continues to be observed as a festival in the English Church, and is marked by the shutting of many of the public offices. The popular name for the festival is *Twelfth Day*, with reference to its occurring twelve days after Christmas. Twelfth Day, and more particularly Twelfth Night, are distinguished by joyful observances. It is a tradition of the Romish Church, that the three wise men were kings, and many sets of names have been furnished for them, Caspar, Melchior, and Balthazar being the set best known: their remains were said to have been recovered in the fourth century by the Empress Helena, and the skulls are still shown, under circumstances of great pomp and ceremony, in the great church at Cologne. Perhaps it is owing to this idea of the regal rank of the wise men, that a custom has existed from early ages throughout Europe of choosing a person to act as king on Epiphany. In England this custom has blossomed out a little. Both a king and queen were chosen. It was done by placing beans on a large cake. The cake was divided among the company, and whoever of the male sex got a bean was king, whoever of the female sex queen. Latterly, other characters have been added, and these were expressed on slips of paper. The Twelfth Night cake continues to be eaten by merry companies, and the characters of king, queen, &c. being drawn in that manner, are supported amidst much jocularity till midnight. There is reason to suppose that the custom of choosing a king is also connected with ancient heathen rites, as in Rome a king of the Saturnalia was chosen by beans. Twelfth cake in England is generally covered

No. 78.

with hardened white sugar and many little ornaments, and its abundant appearance in the windows of bakers and confectioners on this day never fails to arrest the attention of strangers. In Scotland there is not, so far as we can learn, the least trace of either a religious or popular observance of Twelfth Day.

Shakspeare has shown the respect in which the observances of 'Twelfth Night' were held in the Elizabethan age, by applying it as a title to one of his most delightful dramas, although he does not appear to have introduced any of the festivities peculiarly appropriate to that season, with the exception perhaps of the gross orgies of Sir Toby Belch and his boon companions.

Till the reign of George III., it was customary at court on Twelfth Night to hold a public assembly for playing the game of *basset*, in which the king and royal family took part, the winnings being for the benefit of the groom-porter, an officer who in those days had an especial charge of the games of chance played in the palace, at which he acted as umpire.

The day after Twelfth Day was a popular rustic festival, under the mock name of *St Distaff's* or *Rock Day*. (Rock is the appellation given to a quantity of lint put upon a distaff.) It seems to have been a sort of farewell to the festivities of Christmas.

18. *Septuagesima Sunday*.—[It is necessary here to mention that the Movable Feasts and Holy-Days of the church are nearly all regulated by Easter—that is, so long before or after Easter. Easter, the great festival of the church, is itself movable. According to canonical regulations, Easter-day is always the first Sunday after the full moon which happens upon, or next after, the 21st day of March; and if the full moon happens upon a Sunday, Easter Sunday is the Sunday after. The first of these movable feasts is Septuagesima Sunday, which occurs on January 18th, when Easter Sunday is on March 22d. In this place we propose setting down the movable feasts on the earliest days on which they ever occur; and Septuagesima Sunday is therefore put under January 18th. All the rest will follow in order, as in the calendar for a year on which they occur on the earliest possible day.] Quadragesima is an ancient name of Lent, as meaning the forty days' fast. The first Sunday in Lent hence received the name of Quadragesima. Early in the seventh century, Pope Gregory appointed three Sundays of preparation for Lent, and, assuming a decimal reckoning for convenience, they were respectively called, reckoning backwards, Quinquagesima, Sexagesima, and Septuagesima.

21. *St Agnes's Day*, a festival of the Church of Rome. The annals of canonisation present no image of greater sweetness and purity than St Agnes. She is described as a very young and spotless maid, who suffered martyrdom in the tenth persecution under Dioclesian, in the year 306. A few days after her death, her parents, going to make the offerings of affection at her tomb, beheld a vision of angels, amidst which stood their daughter, with a snow-white lamb by her side. She is therefore usually represented with a lamb standing beside her. Perhaps this legend has been partly founded on the resemblance of the name Agnes to *Agnus*, Latin for a *lamb*, for mere coincidences of sound often led to very important ideas in the middle ages. At Rome, on St Agnes's Day, during mass, and while the Agnus is saying, two lambs as white as snow, and covered with finery, are brought in and laid upon the altar. Their fleeces are afterwards shorn and converted into palls, which are highly valued.

Throughout the Christian world, and in England as much as elsewhere, it was customary for young women

on St Agnes's Eve to endeavour to divine who should be their husbands. This was called *fasting St Agnes's Fast*. The proper rite was to take a row of pins, and pull them out one after another, saying a *pater-noster*, and sticking one pin in the sleeve. Then going to rest without food, their dreams were expected to present to them the image of the future husband. In Keats's poem, entitled 'The Eve of St Agnes,' the custom is thus alluded to:—

They told her how upon St Agnes' Eve,  
Young virgins might have visions of delight,  
And soft adorings from their loves receive,  
Upon the hotted middle of the night,  
If ceremonies due they did aright;  
As, suppersless to bed they must retire,  
And couch supine their beauties, lily-white;  
Nor look behind, nor sideways, but require  
Of heaven with upward eyes for all that they desire.

25. *Sexagesima Sunday*; eight weeks before Easter. *Conversion of St Paul*.—A festival of the Romish and English churches, and in London a holiday at the public offices, excepting the Excise, Stamps, and Customs. The populace in former times thought this day prophetic as to the weather of the year:—

If St Paul's Day be fair and clear,  
It doth betide a happy year;  
If blustering winds do blow aloft,  
Then wars will trouble our realm full oft;  
And if it chance to snow and rain,  
Then will be dear all sorts of grain.

In Germany, when the day proved foul, the common people used to drag the images of St Paul and St Urban in disgrace to duck them in the river.

30. *The Martyrdom of King Charles I.*—A holiday of the English Church, in whose behalf Charles is held to have lost his life; observed by the closing of all the public offices, except the Stamps, Excise, and Customs. A motion in the house of Commons in 1772, to repeal as much of the act of 12th Charles II., cap. 30, as relates to the ordering of the 30th of January to be kept as a day of fasting and humiliation, was lost by 125 against 97. The sheet in which the head of Charles was received upon the scaffold, presenting large black stains from his blood, together with his watch, are preserved at Ashburnham Church in the county of Sussex, having been given at the time to his friend Lord Ashburnham. The cap, of laced satin, which he wore on the scaffold, and which he directed to be sent to his friend the Laird of Carmichael in Scotland, passed through the hands of that gentleman's descendants, the Earls of Hyndford, and is now, or was lately, the property of Robert Logan, Esq., residing at New Lanark.

*Natural History.*—January, in our climate, is the coldest month of the year, on an average; for in some years February and March are both colder. The store of heat acquired in summer is now completely dissipated, and the sun has not yet attained sufficient power to replace it. In the central parts of the island of Great Britain, the general average of the thermometer this month is 37 degrees. Vegetation is nearly at a stand during January. Our ancestors thought it necessary that it should be a severe month, for the sake of the rest of the year. This mode of judging, however, is not confirmed by modern experience; for a mild winter is often followed by a warm summer. In sheltered situations a few flowers, as the crocus, mezezon, and polyanthus, are occasionally seen to blossom in the latter part of January; and about the same time (in England) the hedge-sparrow, thrush, and wren begin to pipe.

FEBRUARY.

The establishment of February as the second month of the year by Numa Pompilius has already been mentioned. According to Ovid in his 'Fasti,' a curious record of Roman customs, all objects which were thought to have the effect of moral purgation in the religious ceremonials of that people were called *Februa*. Ceremonials of this kind took place at this season;

hence the name of the month. The vanity of Augustus is said to have been the cause of this month being so much shortened. The arrangement of Julius Cæsar seems to have contemplated an alternation of months of thirty with those of thirty-one days. August was one of thirty days; but when Augustus gave it his name, he could not endure that it should be one of the shorter class, and therefore gave it an additional day, at the expense of February, already one of that class. Our Saxon ancestors called February *sprout hale*, from the sprouting of the cabbage, still called kale in Scotland.

1. *Quinquagesima Sunday*; seven weeks before Easter: called also Shrove Sunday.

2. *Candlemas Day*, or the Purification of the Virgin, a festival of the Church of Rome, and holiday in the English Church. It is said to have been founded upon Roman rites in which candles were carried. The early fathers of the church held it in commemoration of the attendance of Mary in the Temple, forty days after child-birth, as commanded by the law; and it was their custom on this day to bless candles and distribute them among the people, by whom they were carried in solemn procession. The saying of Simeon respecting the infant Christ in the Temple, that he would be a *light* to lighten the Gentiles, probably supplied an excuse for adopting the candle-bearing procession of the heathen, whose external religious practices the founders of the Romish Church made a practice of imitating, in order to take advantage of the habits of the people. Apparently in consequence of the celebration of Mary's purification by candle-bearing, it became customary for women to carry candles with them when, after child-birth, they went to be *churched*. It was to this custom that William the Conqueror referred in his famous remark on a jest of the king of France. The latter hearing that William seemed too fat and unwieldy to take the field, said, 'Methinks the king of England lies long in childbed.' 'When I am churched,' said William, 'there will be a thousand lights in France.' And history knows he made good his boast.

Candlemas Day is a holiday at the public offices, excepting the Stamps, Excise, and Customs. It is called a Grand Day in the Inns of Court, a Gaudy Day at the two universities, and a Collar Day at St James's, being one of the three great holidays, during the terms, on which all legal and official business is suspended.

There is an ancient superstitious notion, universal in Europe, that if Candlemas be a sunshiny day, the winter is not half finished. The Germans say—The badger peeps out of his hole on Candlemas Day, and if he finds snow he walks abroad; if he sees the sun shining, he draws back again into his hole. It is, or rather was, an ancient custom in Scotland for scholars on this day to make presents of money to their masters, and to enjoy it as a holiday.

3. *St Blaise's Day*.—St Blaise, who has the honour of a place in the Church of England calendar, was a bishop of Sebaste in Armenia, and suffered martyrdom in 316. He is the patron saint of the craft of wool-combers, and his name was once considered potent in curing sore throats. At Bradford there is still a septennial procession of the wool trade upon his day. Formerly, it was celebrated extensively by fires lighted on hills, and this is still done in Scotland on the previous evening, under the name of the *Candlemas Blaze*, the resemblance of the name Blaise to blaze having apparently suggested the practice.

*Shrove Tuesday*.—According to the plan already laid down, we place Shrove Tuesday upon this day of the month of February. As the day before the commencement of Lent, it has been from an early age celebrated throughout Christian Europe by feasting and merry-making of such an extravagant nature, as to appear designed to impart a disgust with all such indulgences, in order to make the subsequent mortifications less felt. It is the concluding day of the time of Carnival, which in various Catholic countries is of greater or less extent, but celebrated with most distinction at Venice

and Rome. Carnival is obviously a term from *caro* and *vale*, as meaning a farewell to flesh, this article of food being unused during the whole of Lent. In these two Italian cities, and partially in many others, the Carnival is distinguished by shows, masquerades, races, and a variety of other exhibitions and amusements. The people may be said to live for several days in public. The wealthier classes parade about in their carriages, from which they pelt each other with sweetmeats. Whim and folly are tolerated in their utmost extent, so that only there be nothing said or done to burlesque ecclesiastical dignitaries. In Germany the masquings and mummings of the time of Carnival, called there *Faschings*, are said to have given birth to the dramatic literature of the country.

The main distinction of Shrove Tuesday, in the early times of our own history, was the eating of pancakes made with eggs and spice. The people indulged in games at football, at which there was generally much license; also in the barbarous sport of *throwing at cocks*. In the latter case, the animal being tied by a short string to a peg, men threw sticks at it in succession, till an end was put to its miseries and its life at once. Cockfights were also common on this day, not only amongst the rustics, but at the public schools, the masters condescending to receive the defeated and slain cocks as a perquisite. The festive and mirthful observances of Shrove Tuesday are now much decayed; but the eating of pancakes or fritters still continues. And in some parts of the country, when young people have met together for the festivities of the evening, it is customary for the individual to whose lot it falls to make the pancakes, to put a ring in the dish containing the materials of which they are to be composed; and the person who has the good fortune to receive the cake containing the ring is to be first married.

4. *Ash Wednesday*, the first day in Lent, a holiday of the Church of England, observed by the closing of all the public offices, excepting the Stamps, Excise, and Customs. The palms or substitute branches, consecrated and used on Palm Sunday of one year, were kept till the present season of another, when they were burnt, and their ashes blessed by the priest and sprinkled on the heads of the people: hence the name given to the day. This sprinkling of ashes was performed with many ceremonies and great devotion. On this day also persons convicted of notorious sin were put to open penance. In England it is still a season for the saying of the 'commination' in the Prayer-book, by which the doers of certain kinds of wickedness are cured.

8. *First Sunday in Lent*.—The Wednesday, Friday, and Saturday after this Sunday are called *Ember Days*, and the week in which they occur *Ember Week*. On *Ember Days* our forefathers ate no bread but what was baked in a simple and primitive fashion under hot ashes; hence the name. The other *Ember Days* of the year are the Wednesdays, Fridays, and Saturdays after the Feast of Pentecost, Holyrood Day (Sept. 14), and St Lucia's Day (Dec. 15).

14. *St Valentine's Day*.—St Valentine was a priest of Rome, martyred in the third century, but he seems to have had no connection with the notions and practices to which his day has since been given up. This, it is scarcely necessary to say, is a day thought to be especially devoted to the business of Cupid and Hymen. Possibly its being about the season when the birds choose their mates may be the origin of this belief. Antiquaries have also pointed out that the *Lupercalia*—feasts of ancient Rome in honour of Pan and Juno—were held at this time, and that amongst the ceremonies was a game in which young persons of the opposite sexes chose each other jocularly by lot.

St Valentine's Day is now almost everywhere a degenerated festival, the only observance of any note consisting in the sending of anonymous letters, by way of practical joke, and this confined very much to the humbler classes. The approach of the day is heralded by the appearance in the printsellers' shop windows of vast numbers of missives calculated for use on this

occasion, each generally consisting of a single sheet of paper, on the first page of which is seen some ridiculous coloured caricature of the male or female figure, with a few burlesque verses below. More rarely, the print is of a sentimental kind, such as a view of Hymen's altar, with a pair undergoing an initiation into wedded happiness before it, while Cupid flutters above, and hearts transfixed with his darts decorate the corners. These are paltry frivolities compared with the observances of St Valentine's Day at no remote period. Ridiculous letters were then unknown; and if letters of any kind were sent, they contained only a courteous profession of attachment from some young man to some young maiden, honied with a few compliments to her various perfections, and expressive of a hope that his love might meet with return. But the true proper ceremony of St Valentine's Day was the drawing of a kind of lottery, followed by ceremonies not much unlike what is generally called the game of forfeits. Misson, a learned traveller of the early part of the last century, gives apparently a correct account of the principal ceremonial of the day. 'On the eve of St Valentine's Day,' he says, 'the young folks in England and Scotland, by a very ancient custom, celebrate a little festival. An equal number of maids and bachelors get together; each writes his or her true or some feigned name upon separate billets, which they roll up, and draw by way of lots, the maids taking the men's billets, and the men the maids'; so that each of the young men lights upon a girl that he calls his *valentine*, and each of the girls upon a young man whom she calls hers. By this means each has two valentines; but the man sticks faster to the valentine that is fallen to him than to the valentine to whom he is fallen. Fortune having thus divided the company into so many couples, the valentines give balls and treats to their mistresses, wear their billets several days upon their becoms or sleeves, and this little sport often ends in love.'

In the various jesting ceremonies of the day, there always seems to have been a disposition to believe that the person drawn as a valentine had some considerable likelihood of becoming the associate of the party in wedlock. At least we may suppose that this idea would be gladly and easily arrived at, where the party so drawn was at all eligible from other considerations. The common people seem to have imagined that an influence was inherent in the day, which rendered in some degree binding the lot or chance by which any youth or maid was now led to fix attention on a person of the opposite sex. It was supposed, for instance, that the first unmarried person of the other sex whom one met on St Valentine's morning in walking abroad, was a destined wife or husband.

15. *Second Sunday in Lent*.

22. *Third Sunday in Lent*.

24. *St Matthias the Apostle*.—A festival of the Church of England. St Matthias was chosen by lot after the Crucifixion, in place of the traitor Judas (Acts i. 23).

*Natural History*.—The popular voice allots a course of snow, rain, and their hybrid sleet, to this month, and considers it necessary that such should be its features, in order that all the powers of humidity may be exhausted before the commencement of March, when an opposite kind of weather is looked for. It is indeed true that frost, followed by regular thaw, and that succeeded by the sharp drying winds of March, bring the ground into the most favourable state for ploughing and seed-sowing. The general average of the thermometer is 39 degrees; that of different years varies from 32 to 42. The snowdrop and crocus are the chief ornaments of our flower-borders at this season. The primrose will also flower; the hepatica come forth in some strength; and in mild seasons several other of our earlier flowers and flowering shrubs begin to show blossom. In England the raven and rook begin to build their nests; the house-pigeon has young; the ringdove coo, the goldfinch sings, and thrushes pair. In Scotland the notes of the thrush and blackbird give token of the approach of spring.

## MARCH.

March, which with the ancients ranked the first month of the year, was named in honour of Mars, the god of war, and the supposed father of the founder of Rome. Our Anglo-Saxon ancestors called it *Lent Monath*—that is, Lent or Spring Month.

1. *Mid Lent Sunday*.—A holiday of the Church of England. It was considered as incumbent upon all true Christians on this day to pay a visit, if possible, to their mother church, or church of their native parish, and there make some small offering. The epistle for the day accordingly contains an appropriate allusion—*Hierosolyma mater omnium*, Jerusalem the mother of all (Gal. iv. 21). And it was customary on the same day for people to visit their parents, carrying with them some gift, and receiving the parental blessing in return, together with a mess of furmety—that is, a porridge composed of whole grains of wheat, boiled in milk, and sweetened and spiced. This practice was called 'going a-mothering,' and the day was sometimes called *Mothering Sunday*. The festival, with all its peculiar observances, is supposed to have taken its rise in the heathen festival of the Hilaria, celebrated by the ancient Romans in honour of the mother of the gods, on the ides of March.

*St David's Day*.—The interest attached to this saint and his day is confined to the Welsh, whose patron saint St David is considered. The most rational accounts of St David represent him as Archbishop of Menevy (since, from him, called St David's) in the sixth century. He is said to have been the illegitimate son of a prince of Cardigan, and uncle of the famous, but more than half fabulous, King Arthur. Learning, and more particularly asceticism, the great sources of promotion in those days, raised him to high esteem and ecclesiastical rank, and gave him the reputation of a power to perform miracles. At a synod called at Brevy in Cardigan, in 519, in consequence of the Pelagian heresy, he made an eloquent and convincing display against the erroneous doctrines, which were therefore condemned. He died in 544, at an advanced age, and was buried in the church of St Andrew, but in 962 his remains were transferred to Glastonbury Abbey.

While the Welsh venerate the memory of St David, they are unacquainted with our idea of him as their patron saint, a notion which has sprang up in consequence of the popular fiction of the Seven Champions of Christendom. They observe the 1st of March as the anniversary of his death. On this day all true Welshmen, whether in their own country or far removed from it, make it a point of conscience to wear a leek in their hats; and this custom is alluded to in writings of considerable antiquity. It has also been made effective use of by Shakespeare in his historical drama of 'King Henry V.:' and the heroic cudgelling which he there represents the choleric Welshman Fluellen as having administered to Ancient Pistol when he compelled him to eat the leek which he had mocked at on 'St Tavy's Day,' has given rise to a proverbial saying; for of an individual who has been forced to do anything contrary to his own inclination, it is by no means uncommon to say that he has been made 'to eat his leek.' How the leek has become connected with St David and the affections of Welshmen is not ascertained. The most probable story is, that at a great battle between the Welsh and Saxons in the sixth century, the former, by advice of St David adorned their hats with leeks, for the sake of distinction from their enemies, taking the herb from a neighbouring field, where they grew in abundance. The victory gained by the Welsh being partly attributed to this cause, the leek was ever after held in veneration, and associated with the name of St David. 'The most honourable and loyal society of Ancient Britons,' instituted in London in 1714, and who support a school in the metropolis for the support and education of poor Welsh children, have an annual procession

on St David's Day, on which occasion each member wears a representation of the leek in his hat, the marshals in front being decorated in like manner. In the household expenses of the Princess Mary, in 1544, there is entered a gift of fifteen shillings to the yeomen of the king's guard for bringing a leek to her grace on St David's Day.

8. *The Fifth Sunday in Lent*.—It was popularly distinguished as *Care* or *Carling Sunday*, terms which appear to be of very dubious import. The peasantry and yeomanry used to steep peas and afterwards parch them, and then, frying them with butter, made a feast of them on the afternoon of this day. It is thought not unlikely that the custom bore some reference to the superstitious notions which the ancients entertained respecting beans, as containing the souls of the departed. The peas, as eaten in the north of England, were called *carlings*. We may presume that the day took its name from this word, *carling* being in time softened into *Care*. It figures in the following old rhyme which enumerates the Sundays of Lent by popular appellations—

Tid, Mid, and Misera,  
Carling, Palm, and good Pace-day.

The three first words are supposed to have been derived from the beginnings of certain psalms—thus, *Te deum, Mi deus, Miserere mei*.

15. *Palm Sunday*, called in the English Prayer-book the Sunday next before Easter; also sometimes called Passion Sunday, as being the commencement of Passion Week, or the week celebrative of the sufferings or passion of our Lord. It is a festival of great antiquity and a partly joyous character, as more particularly commemorating the brilliant though short-lived popularity of the reception which Christ met with on entering Jerusalem immediately before his passion. On this day, in Catholic countries, the priests bless branches of palm, or some other tree, which are then carried in procession, in memory of those strewed before Christ at his entrance into the holy city. The procession is as splendid as circumstances will admit of; and after it is done, the boughs used on the occasion are burnt, and their ashes preserved, that they may be laid on the heads of the people next Ash Wednesday, with the priest's blessing.

After the Reformation, 1536, Henry VIII. declared the carrying of palms on this day to be one of those ceremonies not to be contemned or dropped. The custom was kept up by the clergy till the reign of Edward VI., when it was left to the voluntary observance of the people. Fuller, who wrote in the ensuing age, speaks of it respectfully, as 'in memory of the receiving of Christ into Hierusalem a little before his death, and that we may have the same desire to receive him into our hearts.' It has continued down to a recent period, if not to the present day, to be customary in many parts of England to go *a-palming* on the Saturday before Palm Sunday; that is, young persons go to the woods for slips of willow, which seems to be the tree chiefly employed in England as a substitute for the palm, on which account it often receives the latter name. They return with slips in their hats or button-holes, or a sprig in their mouths, bearing the branches in their hands. Not many years ago, one stall-woman in Covent-Garden market supplied the article to a few customers, many of whom, perhaps, scarcely knew what it meant. Slips of the willow, with its velvety flower-buds or catkins, are still stuck up in some rural pariah churches in England.

17. *St Patrick's Day*, a high festival of the Romish Church. The interest attached to this saint and his day is, however, chiefly confined to the Irish, whose patron saint he is considered; though that term, as in the case of St David, is of modern and English origin. The Irish venerate St Patrick as the person who introduced Christianity into their country. He is said to have been born at Kilpatrick, near Dumbarton in Scotland, and to have first visited Ireland as a boy and a

## KEY TO THE CALENDAR.

prisoner. Afterwards travelling into Gaul and Italy, and growing up as a learned priest, he was commissioned by Pope Celestine to convert the Irish, a task which he immediately commenced, and carried into effect with unexampled ardour and perseverance. He travelled throughout the whole of Ireland, preaching everywhere to the barbarous people, whom he baptised in multitudes. He also ordained clergy to preside over them, gave alms to the poor, made presents to the kings, founded monasteries, and, in short, established the Christian religion and a full apparatus for its support in Ireland. Monkish annals and popular tradition attribute to him an immense number of miracles, most of which have probably no basis in fact. He died, in 432, at Down in Ulster, and was there buried.

As the Welsh are solicitous to display the leek on St David's Day, so are the Irish to show the *shamrock* on that of St Patrick. The shamrock is a bunch of trefoil, a species of grass. It is associated with St Patrick and his day in consequence, as popular story goes, of the saint having made a very adroit use of the plant in his first preaching, immediately after landing. The people being staggered by the doctrine of the Trinity, and disposed to show some violence to him, he took up a trefoil growing by his side, and illustrated the point by showing its three blades growing on one stalk; whereupon they were immediately convinced, and became converts. In Dublin, St Patrick's Day is, or was lately, a scene of festivity and mirth unparalleled. 'From the highest to the lowest,' says Mr Hone, 'all seem inspired by the saint's beneficence. At daybreak flags fly from the steeples, and the bells ring out incessant peals till midnight. The rich bestow their benevolence on the poor, and the poor bestow their blessings on the rich, on each other, and on the blessed St Patrick. The "green immortal" shamrock is in every hat. Sports of manly exercise exhibit the capabilities of the celebrated shillelah. Priestly care soothes querulousness; laughter drowns casualty; lasses dance with lads; old women run about to share cups of consolation with each other; and by the union of wit, humour, and frolic, this miraculous day is prolonged till after the dawn of next morning.'

19. *Maundy Thursday*, called also *Shere Thursday*, the day before Good Friday. Its name of *Shere Thursday* appears to have arisen from the practice which the priests had of shearing their hair on this day, to make themselves as trim as possible for Easter. The other name is more doubtful, but seems most probably to have been derived from *maund*, an old English word for a basket, in consequence of the distribution of gifts on this day in baskets—the word *maundy*, used by old authors for alms or gifts, being apparently derived in its turn from the practice of this day. The religious customs of the day consisted in works of humility, and in conferring gifts on the poor. The object seems to have been to commemorate, or imitate, the humility of Christ in washing the feet of his disciples—the giving of maundies being an additional good work. Cardinal Wolsey, at Peterborough Abbey, in 1530, 'made his maund in our lady's chapel, having fifty-nine poor men whose feet he washed and kissed; and after he had wiped them, he gave every of the said poor men twelve pence in money, three ells of good canvas to make them shirts, a pair of new shoes, a cast of red herrings, and three white herrings; and one of these had two shillings'—the number of the poor men being probably in correspondence with the years of his age. Even royalty condescended to this practice. The king of England was accustomed on Maundy Thursday to have brought before him as many poor men as he was years old, whose feet he washed with his own hands, after which his majesty's maunds, consisting of meat, clothes, and money, were distributed amongst them. Queen Elizabeth, when in her thirty-ninth year, performed this ceremony at her palace of Greenwich, on which occasion she was attended by thirty-nine ladies and gentlewomen. Thirty-nine poor persons being

assembled, their feet were first washed by the yeomen of the laundry with warm water and sweet herbs, afterwards by the sub-almoner, and finally by the queen herself, kneeling; these various persons, the yeomen, the sub-almoner, and the queen, after washing each foot, marked it with the sign of the cross above the toes, and then kissed it. Clothes, victuals, money, and other gratuities were then distributed.

This strange ceremonial, in which the highest was for a moment brought beneath the lowest, was last performed in its full extent by James II. King William left the washing to his almoner; and such was the arrangement for many years afterwards. 'Thursday, April 15 [1731], being Maundy Thursday, there was distributed at the Banqueting House, Whitehall, to forty-eight poor men and forty-eight poor women (the king's [George II.] age being forty-eight), boiled beef and shoulders of mutton, and small bowls of ale, which is called dinner; after that large wooden platters of fish and loaves—namely, undressed, one large old ling, and one large dried cod; twelve red herrings and twelve white herrings, and four half-quarter loaves. Each person had one platter of this provision; after which were distributed to them shoes, stockings, linen and woollen cloth, and leathern bags, with one penny, twopenny, threepenny, and fourpenny pieces of silver and shillings—to each about four pounds in value. His Grace the Lord Archbishop of York, Lord High Almoner, performed the annual ceremony of washing the feet of a certain number of poor in the Royal Chapel, Whitehall, which was formerly done by the kings themselves, in imitation of our Saviour's pattern of humility.' For a considerable number of years the washing of the feet and other ceremonies has been entirely given up; and since the beginning of the reign of Queen Victoria, an additional sum of money has been given in lieu of provisions.

20. *Good Friday*.—This day, as the presumed anniversary of the Crucifixion, has for ages been solemnly observed throughout Christian Europe, the only exceptions being in Presbyterian countries, such as Scotland. In Catholic times, the observances of the day in England were of the same character with those which are still maintained in many parts of the continent. It is still a solemn festival of the Church of England, and the only one besides Christmas which is honoured by a general suspension of business. Strictly observant Church-of-England people abstain from all kind of animal food, even from cream to tea; such, we are informed by Boswell, was the custom of Dr Johnson. The churches are in general well attended, and it is considered proper to appear there in black clothes.

Amongst the usages of this day was a strange ceremony of creeping to the cross, which even the king was not exempt from performing. The king also distributed rings at Westminster Abbey for the cure of the cramp. The ceremonious burying of a crucifix, as representing the burial of Christ, is calculated to give less surprise. It is still in some measure kept up in the service of the *Tenebrae*, performed in St Peter's at Rome. It was also customary at great churches to have a small building in the form of a tomb, in which the host was this day deposited, by way of representing the burial of Christ. In England, and perhaps also in other countries, eggs and bacon were the kinds of food appropriate to Good Friday. The eggs laid on this day were thought to have the power of extinguishing any fire into which they might be thrown. In modern times, the only species of viands connected with Good Friday in Britain is the well-known hot cross bun, a small spiced cake, marked with the figure of a cross, and sold not only in bakers' shops but by persons traversing the streets with baskets.

In London, as well as in almost every other considerable town in England, the first sound heard on the morning of Good Friday is the cry of 'Hot Cross Buns!' uttered by great numbers of people of a humble order, who parade the streets with baskets containing a plentiful stock of the article, wrapped up

in flannel and linen to keep it warm. The cry, which is rather musical, is strictly—

Hot cross buns—  
One a penny, buns—two a penny, buns;  
One a-penny, two a-penny—hot cross buns.

Hucksters of all kinds, and many persons who attempt no traffic at any other time, enter into the business of supplying buns on Good Friday morning. They make a stir on the streets, which lasts till church time, and it is resumed in the afternoon. About a century ago there was a baker's shop at Chelsea, so famous for its manufacture of excellent buns, that crowds of waiting customers clustered under its porch during a great part of the day. The buns were brought up from the oven on small black tin trays, and so given out to the people. The king himself had stopped at the door to purchase hot cross buns, and hence the shop took the name of the Royal Bun-House. As always happens in London when anything original and successful is struck out, the Royal Bun-House soon obtained a rival, and was obliged to advertise as the Old Original Royal Bun-House. The wars of these two houses, like those of York and Lancaster, have long since been hushed to rest; and we find it stated in a recent work [Mr Hone's amusing 'Every-Day Book,' vol. i. p. 404] that neither of them is now distinguished for this article above the other bakers' shops of Chelsea.

In old times, Good Friday was distinguished in London by a sermon preached at *Paul's Cross* (a wooden pulpit placed on stone steps, and surmounted by a cross, which stood till the time of the civil war, in the open air, near the north-east corner of St Paul's Cathedral). The sermon was generally on the subject of Christ's passion. Connected with it, two or three others were preached on Monday, Tuesday, and Wednesday, in Easter week, at the Spital in Spitalfields, where the Lord Mayor and all the most eminent persons in London generally attended. The 'Spital sermons' are still kept up, but take place in St Bride's Church.

21. *Easter Eve*.—In Catholic times, it was customary to put out all fires on this day, and light them anew from flint. The priest blessed the new fire, and a brand from it was thought to be an effectual protection against thunder-strokes. A large wax taper, called the *Pascal Taper*, was also blessed, and lighted beside the representative sepulchre above-mentioned, and there a vigil was kept till morning. The taper used on one of these occasions in Westminster Abbey church is said to have been 300 pounds in weight.

22. *Easter Day*, a solemn festival in celebration of the Resurrection. The word used by us is from the Saxon *oster* (rising). Easter is observed with much ceremonial, not only throughout Catholic Europe, and in the countries where the Greek church is established, but in Turkey and the Mohammedan countries along the coast of Africa. The festival is an engrafment upon the Jewish *Passover*, the name of which (*pascha*) is still applied to it in almost every country besides England. The Catholic observances of Easter are of an elaborate character. At Rome, the Pope is carried in state to perform high mass in St Peter's, from the balcony of which he afterwards blesses the people assembled in the piazza below—perhaps one of the most imposing religious spectacles which the world anywhere presents. In England, before the Reformation, the Catholic observances of Easter were as fully enacted as in any other country. Early in the morning, a sort of theatrical representation of the Resurrection was performed in the churches, the priests coming to the little sepulchre where, on Good Friday, they had deposited the host, which they now brought forth with great rejoicings, as emblematical of the rising of the Saviour. In the course of the day, the clergy had a game at ball in the church, a custom of which it is now difficult to believe that it ever could have existed.

At present, in large seats of population, Easter Sunday is distinguished by little besides the few peculiarities of the service, and the custom of going to church

in attire as gay as possible. But in rural districts there still exist a few vestiges of old superstitions and customs connected with the day. It was once a general belief, and probably still is so in a few out-of-the-way places, that on Easter morning the sun danced or played immediately after his rising. People rose early, and went into the fields to see this supposed phenomenon.

The viands appropriate to Easter Day in the old times were, first and above all, eggs, then bacon, tansy pudding, and bread and cheese. The origin of the connection of eggs with Easter is lost in the mists of remote antiquity. They are as rife at this day in Russia as in England. There it is customary to go about with a quantity, and to give one to each friend one meets, saying, 'Jesus Christ is risen,' to which the other replies, 'Yes, he is risen,' or, 'It is so of a truth.' The Pope formerly blessed eggs to be distributed throughout the Christian world for use on Easter Day. In Germany, instead of the egg itself, the people offer a print of it, with some lines inscribed. Formerly, the king of England had hundreds prepared to give to his household: in a roll of the expenses of Edward I. the following occurs, in the accounts of Easter Sunday, in the eighteenth year of his reign—'Four hundred and a-half of eggs, eighteenpence.' The custom is supposed to have been originally Jewish.

At this day, the Easter eggs used in England are boiled hard in water containing a dye, so that they come out coloured. The boys take these eggs and make a kind of game, either by throwing [bowling] them to a distance on the green sward—he who throws oftenest without breaking his eggs being the victor—or hitting them against each other in their respective hands, in which case the owner of the hardiest or last surviving egg gains the day.

It was at one time customary to have a gammon of bacon on this day, and to eat it all up, in signification of abhorrence of Judaism. The tansy seems to have been introduced into Easter feasts as a successor to the bitter herbs used by the Jews at the *Passover*. It was usually presented well sugared.

It was a custom in the thirteenth century to seize all ecclesiastics found walking abroad between Easter and Pentecost, and make them purchase their liberty with money. This was an acting of the seizure of the apostles after Christ's passion. We have still what appears to be a relic of this fashion in a custom which exists in various parts of England. A band of young men go abroad, and whatever female they meet they take hold of her, and pull off her shoes, which are only returned to her upon her paying some trifling forfeit. In Durham it is done by boys, who, on meeting any woman, accost her with, 'Pay for your shoes, if you please.' The trifling sums which they thus collect are spent in a feast at night. At Ripon, celebrated for its manufacture of spurs, travellers riding through the town are stripped of those articles, which in like manner they have to redeem. On Easter Monday, the women make a return by going abroad in groups, and causing the men to redeem their shoes.

'Lifting at Easter' is another old custom, which may be presumed to have originated in a design of dramatising the events connected with Christ's passion. It consisted in hoisting individuals up into the air, either in a chair or otherwise, until they relieved themselves by a forfeit. A curious record makes us aware that on Easter day, in the eighteenth year of the reign of Edward I., seven ladies of the queen's household went into the king's chamber and *lifted him*, for which fourteen pounds appears to have been disbursed as a forfeit. The men lifted the women on Easter Monday, and the women claimed the privilege of lifting the men in return on the ensuing day. Three hoists were always given, attended by loud huzzas.

23. *Easter Monday*.—This and the ensuing day are holidays of the church. The week commencing with Easter, and called thence Easter week, is a season of festivity and partial suspension of business; and the

## KEY TO THE CALENDAR.

earlier days of it after Easter itself are in London devoted by the working-classes to recreation and amusement, which they chiefly seek for at Greenwich Fair, and in excursions to taverns near town.

25. *The Annunciation of our Lady*, a festival of the Church of England. It is commonly called in England *Lady-Day*, as an abridgment of the Day of our Blessed Lady. This festival is in celebration of the incarnation of Christ, or the announcement by the Holy Ghost to Mary that she should bear the Son of God. The Annunciation is observed as a holiday at all the public offices, excepting the Stamps, Excise, and Customs. It is a gaudy day in the Romish Church. In Catholic countries the service of this day resounds with 'Hail, Mary!' uttered in a strain of the highest enthusiasm. The 25th of March is held as a quarter-day for many commercial purposes in England.

29. The first Sunday after Easter, called *Low Sunday*, because it is Easter day repeated, with the church-service somewhat abridged or *lowered* in the ceremony from the pomp of the festival the Sunday before.

*Natural History.*—March is eminently a spring month, and the season more particularly devoted to sowing. Its general character, as far as the extreme uncertainty of our climate warns us to speak, is dryness. The frosts of winter, followed by the sharp dry winds of this month, have the effect of pulverising the soil, and fitting it for the reception of the seed. The value of the weather appropriate to March is expressed in the saying, 'A peck of March dust is worth a king's ransom.' This month is also expected to undergo a change between its beginning and its end. The English say 'March comes in like a lion, and goes out like a lamb;' the Scotch version of the same idea is, 'March comes in with an adder's head, and goes out with a peacock's tail.' The general average temperature of March (41 degrees) is so little above that of February, as to make the greater dryness appear to arise in but a small degree from heat. There is in March a general bursting of the trees into leaf, of the meadows into flower, and partly, it may be added, of the birds into song. It is the season for planting gardens, as well as sowing the fields, although in many situations there are few which may not be deferred for a little longer without disadvantage.

### APRIL.

The Romans gave this month the name of *Aprilis*, from *aperis*, because it was the season when things opened. By the Saxons it was called *Ostre month*, probably from the same word from which Easter is supposed to have been derived. The Dutch and Germans term it *Gras month*.

1. *All Fool's Day.*—From a very early age, this day has been considered as one set apart for the exercise of all kinds of mirthful folly and practical joking: the term given to it we may hold as a travesty of the festival of All Saints' Day. The custom of playing off little tricks on this day, whereby ridicule may be fixed upon unguarded individuals, appears to be universal throughout Europe. In France, one thus imposed upon is called *Un poisson d'Avril* (an April fish). In England, such a person is called an April fool; in Scotland, a gowk. Gowk is the Scotch for the cuckoo, and also signifies a foolish person, being in fact from the same root as the English word gawky. The favourite jest in Britain is to send one upon an errand for something grossly nonsensical—as for pigeon's milk, or the History of Adam's Grandfather; or to make appointments which are not to be kept; or to call to a passer-by that his latchet is unloosed, or that there is a spot of mud upon his face. When he falls into the snare, the term April fool or gowk is applied with a shout of laughter. It is very remarkable that the Hindoos practise precisely similar tricks on the 31st of March, when they have what is called the Huli Festival.

7. The fifteenth day after Easter is marked by an old English festival, to which the inexplicable term

*Hock Day* is applied. The custom peculiar to the day consisted in the men and women of rural districts going out to the roads with ropes, and intercepting passengers jocularly, and raising money from them, to be bestowed, it may well be presumed, in pious uses.

23. *St George's Day* in the Romish calendar. St George is held as the tutelary or patron saint of England. He is said to have been a native of Cappadocia; and it is tolerably certain that he was held in great veneration by the Greeks in the fourth century. Throughout the countries once constituting the Lower Empire, in the Crimea, and in Tartary, he has for ages been worshipped; in the former countries as a saint, in the latter as a deity. By all he is invariably represented as a man on horseback, spearing a dragon. With a regard apparently to his military character, our Edward III. adopted his name as his war-cry, and his figure as a badge in connection with the order of the garter; thus originated the association of St George with England, since in many respects so conspicuous. It is remarkable that in Russia St George is as much a favourite saint as he is in England. The sovereigns of that country have borne his emblem from a time previous to Edward III. The derivation of Russian Christianity from the Greek Church suggests a ready explanation of this fact. The English do not mark the day of their national saint with any of those observances which give St David's and St Patrick's days so peculiar a character in Wales and Ireland; but it was customary at no distant period for people of fashion to wear a blue coat on this day in honour of St George.

25. *St Mark the Evangelist's Day*, a holiday of the Church of England. It was once customary to bless the fruits of the earth on this day; hence, perhaps, a notion amongst the peasantry, that to plough or do any other work on St Mark's Day will be apt to bring down Divine wrath. The eve of St Mark was distinguished by some superstitious ceremonies. Maidens met to make the *dumb cake*. This was done by a number not exceeding three, and it was to be done in silence. At twelve o'clock, the cake being prepared, each broke off a piece and ate it; then walked backwards to her sleeping-room. It was thought that those who were to be married would hear a noise as of a man approaching. Those who heard nothing were to remain unmarried. Watching the church porch was another practice of this eve. A man went fasting and took his station there before midnight. It was thought that during the hour between twelve and one he would see the spirits of all who were to die in the parish during the ensuing year walk into church, in the order in which they were to die, those who were to perish by violence making gesticulations appropriate to the peculiar modes of their death. There were similar superstitions regarding the Eve of St John (June 24); which see.

26. *Rogation Sunday.*—The Sunday before Ascension is always so called. The three days immediately following are also called Rogation Days. The Archbishop of Vienne in Dauphiné, about the year 469, caused the litanies or supplications to be said on those days for deliverance from earthquakes, by which his city had been much injured. The days were thence called Rogation—that is, supplication—days. They were distinguished by great processions of ecclesiastics throughout the bounds of their districts.

30. *Ascension Day, or Holy Thursday*, a holiday of the Church of England, observed by the shutting of most of the public offices. This festival, which invariably occurs on the fortieth day after Easter, is designed to celebrate the ascension of Christ into Heaven. It was once distinguished by great festivities. On this day, also, there was a custom of the parish schoolmaster going with his pupils round the bounds of the parish, the pupils carrying peeled willow wands, wherewith they struck the boundaries. This was an expedient for keeping those boundaries in memory, in an age when more accurate means of attaining the same end did not exist.

*Natural History.*—Mild weather, with genial showers, is the character usually given to April; but in modern

times the weather is often the reverse of this, being dry, with cold winds. On the average, indeed, there is more north wind and *less rain* this month than in any other. The progressive advance of temperature from winter toward summer is very apparent this month, the general average height of the thermometer being 46 degrees. April is a busy month in the fields, and the usual seed-time for barley. In the gardens it is the busiest time of the year for seed-sowing.

MAY.

Among the Romans, this was the *mensis maiorum*, or month dedicated to the elder persons of their community, while the next was the *mensis juniorum*, or month of the younger people. Thus most probably arose the names of May and June. Others suppose that May would derive its name from Maia, the mother of Mercury, who was worshipped on the first day; but it is not impossible that Maia and her day were afterthoughts, when the real origin of the name of May was out of mind. The Saxons are said to have given this month the strange-looking name of Trimilchi, because they then began to milk their cows three times a day. The Romans believed it to be unlucky to marry in May.

1. *St Philip and St James the Less*, a holiday of the Church of England.

As a popular festival, under the name of *May-Day*, this day has been celebrated from time immemorial. The celebration must doubtless have been prompted by nature herself: the time of the young flower and leaf, and of all the promise which August fulfils, could not but impress the minds of the simplest people, and dispose them to joyful demonstrations in word and act. The sun, as the immediate author of the glories of the season, was now worshipped by the Celtic nations under the name of Baal; hence the festival of *Beltane*, still faintly observed in Ireland and the Highlands of Scotland. Even in Ayrshire, they kindled Baal's fire in the evening of May-day till about the year 1790. The Romans held games called *Floralia*, at which there was great display of flowers, and where women danced, if we are to believe Juvenal, only too enthusiastically. The May-day jollities of modern Europe seem to be directly descended from the *Floralia*.

In England, we have to go back a couple of hundred years for the complete May-day; since then it has gradually declined, and now it is almost extinct. When it was fully observed, the business of the day began with the day itself—that is to say, at midnight. We have the authority of Shakspeare, that with the populace of England it was impossible to sleep on May morning. Immediately after twelve had struck, they were all astir, wishing each other a merry May, as they still, at the same hour on the 1st of January, wish each other a happy new year. They then went forth, with music and the blowing of horns, to some neighbouring wood, where they employed themselves in breaking down and gathering branches. These they brought back at an early hour, and planted over their doors, so that by daylight the whole village looked quite a bower. The citizens of London went a-Maying in this fashion, notwithstanding their comparative distance from woods. They went marshalled in parishes, or in unions of two or three parishes; their mayor and aldermen went also; and we read of Henry VIII. and Queen Catharine riding from Greenwich to Shooter's Hill, attended by lords and ladies, to join in the sport. In some places, the Mayers brought home a garland suspended from a pole, round which they danced. In others, and this was a more general custom, there was an established May-pole for the village, which it was their business to dress up with flowers and flags, and dance around throughout all the latter part of the day. A May-pole was as tall as the mast of a sloop of fifty tons, painted with spiral stripes of black and white, and properly fixed in a frame to keep it erect. Here lads and lasses danced in a joyful ring for hours to the sounds of the viol, and masquers personating Robin Hood,

Little John, Maid Marian, and others of the celebrated Sherwood company of outlaws, as well as morris-dancers, performed their still more merry pranks. May-poles, as tending to encourage levity of deportment, were condemned by the Puritans in Elizabeth's time; James I. supported them in his *Book of Sports*; they were altogether suppressed during the time of the Commonwealth, but got up again at the Restoration. Now change of manners has done that which ordinances of parliament could not do. This object, so interwoven with our national poetical literature, is all but rooted out of the land.

A certain superstitious feeling attached to May-day. The dew of that morning was considered as a cosmetic of the highest efficacy; and women, especially young women, who are never unwilling to improve in this respect, used to go abroad before sunrise to gather it. To this day there is a resort of the fair sex every May-morning to Arthur's Seat near Edinburgh, for the purpose of washing their faces with the dew. Mr Pepps, in his 'Diary,' gravely tells us of his wife going to Woolwich for a little air, and to gather May-dew, 'which Mrs Turner hath taught her is the only thing in the world to wash her face with.' Scott, in his 'Discovery of Witchcraft,' speaks of a sprig of hawthorn gathered on May-day, and hung in the entry to a house, as a presumed preservative against all malign influences. There was also a practice of making fools on May-day, similar to what obtains on the first of the preceding month. The deluded were called *May-goslings*. It was held unlucky to marry in May—a notion which, as already mentioned, existed among the Romans. It still exists in Scotland, where very few marriages take place in May, the higher classes being equally superstitious on the subject with the lower.

In London, as has been said, May-day was once as much observed as it was in any rural district. There were several May-poles throughout the city, particularly one near the bottom of Catharine Street in the Strand, which, rather oddly, became in its latter days a support for a large telescope at Wanstead in Essex, the property of the Royal Society. The milkmaids were amongst the last conspicuous celebrators of the day. They used to dress themselves in holiday guise on this morning, and come in bands with fiddles, whereto they danced, attended by a strange-looking pyramidal pile, covered with pewter plates, ribbons, and streamers, either borne by a man upon his head, or by two men upon a hand-barrow: this was called their *garland*. The young chimney-sweepers also made this a peculiar festival, coming forth into the streets in fantastic dresses, and making all sorts of unearthly noises with their shovels and brushes. The benevolent Mrs Montagu, one of the first of the class of literary ladies in England, gave these home slaves [their liberation was effected in 1841] an annual dinner on this day, in order, we presume, to aid a little in reconciling them to existence. In London, May-day still remains the great festival of the sweeps, and much finery and many vagaries are exhibited on the occasion.

The Robin Hood games and morris-dances, by which this day was distinguished till the Reformation, appear, from many scattered notices of them, to have been entertainments full of interest to the common people. Robin has been alternately styled in at least one document as the King of May, while Maid Marian seems to have been held as the Queen. The various scattered particulars respecting these festivities, which make but dry reading by themselves, have been wrought up to some advantage by Mr Strutt in his 'Queen Hoo Hall,' where he describes May-day as celebrated by the servants and dependants of an English baron of the fifteenth century.

3. *The Invention of the Cross*, a festival of the Romish Church, designed to commemorate the finding of the cross upon which Jesus had suffered, by St Helena. The festival is shortly called *Rood Day*.

10. *Whit-Sunday*, a festival of the Church of England, designed to commemorate the descent of the Holy Spirit

## KEY TO THE CALENDAR.

upon the apostles on the day of Pentecost. In Catholic countries, on this day, while the people are assembled in church, pigeons are suspended above, and wafers, cakes, oak leaves, and other things are made to shower down upon the altar—all this as a dramatic representation of the miracle.

11. *Whit-Monday*.—A festival of the Church of England, as is also

12. *Whit-Tuesday*.—These three days together are called Whitsuntide. It forms a term, for which the 15th of May is fixed. The Wednesday, Friday, and Saturday of this week are Ember Days, and the week is consequently an Ember Week. (See 8th February.) This also was a period of festivity among our ancestors. They now had what they called the *Whitsun Ale*, which consisted in a meeting of householders with their families at the church, after service, to partake of a feast provided by the churchwardens, at which the young danced and played at games, while the seniors looked on. In the days before the poor were supported by rates, a collection was made on this occasion, usually found sufficient to provide for them. The Whitsun Ale is now degenerated, where it exists at all, into a merry-making at a barn. Whitsunday and Martinmas terms (May 15 and November 11) are those alone regarded for the leasing of all kinds of property, paying of rents, and engaging of servants, in Scotland.

17. *Trinity Sunday*, a festival of the Church of England, which always takes place eight weeks after Easter.

21. *Corpus Christi*, a festival of the Romish Church, always held on the Thursday after Trinity Sunday. It celebrates the doctrine of transubstantiation. In all Roman Catholic countries it is observed with music, lights, flowers strewed in the street, rich tapestries hung upon the walls, and processions and plays representing Scripture subjects.

29. *Restoration Day*, a holiday of the Church of England to celebrate the restoration of monarchy in the person of Charles II., May 29, 1660, after its suppression for the preceding twelve years. The populace at one time wore oak leaves in their hats on this day, with reference to the concealment of Charles in the Royal Oak, while skulking after the battle of Worcester 1651.

*Natural History*.—May is a month of the best reputation—indeed a general favourite in imagination; but it often balks the hopes of its worshippers. In favourable seasons, it presents many beautiful appearances, as herbage and foliage of the brightest green, a profusion of natural flowers, soft and genial skies, fishes leaping, swallows twittering, bees humming, the cuckoo repeating her note, and the corn coming into blade. But these appearances are often prevented or much clouded by cold east winds, most destructive to the fruit blossom. The greater prevalence of this wind during May than in any other month, seems to be chiefly the cause of the well-known injunction, 'Change not a clout till May be out.' The general average temperature is about 51 degrees. We are now arrived at the latest period of seed-time. In the most backward parts of the country, barley is still sown; turnip sowing is general; and the seeds of the tenderer garden plants are committed to the earth. The ash, the last-budding of our native trees, comes into leaf in the latter part of the month.

### JUNE.

The probable origin of the name of this has been explained at the same time with that of May.

11. *St Barnabas the Apostle*, a holiday of the Church of England. In the old style, the 11th of June was the longest day; hence an ancient rhyme—

Barnaby Bright,  
The longest day and the shortest night.

15. *St Vitus's Day*.—St Vitus was a Sicilian martyr. From him, though for what reason is unknown, is named a well-known nervous affection of the limbs, proceeding from a disordered state of the visceral sys-

tem. It was a popular belief that rain on this day indicated rain for thirty days thereafter.

24. *St John's Day*, the Nativity of St John the Baptist, a holiday of the Church of England. The *Eve of St John*, variously called *Midsummer Eve*, was formerly a time of high observance amongst the English, as it still is in Catholic countries. Bonfires were everywhere lighted, round which the people danced with joyful demonstrations, occasionally leaping through the flame. A certain number of citizens formed a watch, which perambulated the streets all night. It was also believed that on this eve, by fasting, waking, pulling certain herbs, and going through certain ceremonies, it was possible to obtain an insight into futurity on some important points. *Fasting St John's Fast* was a great feat of young women a century or two ago. There was also a custom of holding vigil in the church-porch, precisely the same as described under St Mark's Day (April 25).

29. *St Peter's Day*, a high festival of the Romish Church, and a holiday of the Church of England. It is celebrated at Rome with illuminations and magnificent ceremonials. In England, till a recent period, the bonfires and watchings of St John's Eve were also customary on the eve of this festival.

*Natural History*.—In the central parts of our island, this is in general a dry coldish summer month. The days, however, are at the longest; and though June ranks only third highest as to temperature, drought or evaporation reaches the extreme point. June here resembles the May of more southern climes. The foliage being now quite fresh and fully expanded, and the verdure of the pastures and corn-fields being also at the best, the face of nature appears to the greatest advantage. Towards the end of the month we meet with a near coincidence of four stages of vegetation—the earing of wheat, the flowering of the rose, the ripening of strawberries, and the commencement of hay harvest. The general average of the thermometer is 57 degrees. In the course of the month we have the flowering of a great number of fine perennials and shrubs, so that the gardens are usually in great glory. It is also the time when weeds give the gardener and husbandman the greatest trouble.

### JULY.

This, being at first the fifth month of the Roman year, was called Quintilis. It became the seventh in consequence of the reform of the calendar by Julius Cæsar, in whose honour, as he was born in it, Augustus gave it the present name.

3. The day fixed in the calendars as the first of the *Dog-Days*, the last being the 11th of August. The dog-days precede and follow the heliacal rising of the star Sirius (in the constellation of the Greater Dog) in the morning, which in Pliny's time was on the 18th of July. The extreme heat of this season of the year, although to us palpably the effect of the continued high position of the sun, was connected by the ancients with the appearance of this star in the morning. They considered the dog-star as raging, and gave the time the appellation of the *Dog-Days*. The liability of dogs to rabies in consequence of the heat of the season was connected with the same star, though there was nothing but accident in the collusion; and they butchered these animals without mercy. At Argos, there was a festival expressly instituted for the *killings of dogs* during this season. By the precession of the equinoxes, the heliacal rising of Sirius in the morning has been changed to the latter end of August, and in a few thousand years more it will take place in the depth of winter.

4. *The Translation of St Martin Bullion*, noticed as a festival in the Church of England calendar, though not observed. There is an old saying, not heretofore in print, 'If the deer rise up dry and lie down dry on St Bullion's Day, it is a sign there will be a good goose har'st;' meaning, apparently, that dry weather at this season is favourable to the crops.

*St Ulric's Day.*—On this day, in ancient Catholic times, the people brought fish to the altar to obtain the favour of St Ulric, and one sat there selling the same back to the public for the benefit of the Church.

7. *The Translation of St Thomas à Becket*, noticed as a festival in the Church of England calendar.

15. *St Swithin's Day*—remarkable on account of a well-known popular notion, that if it rain on this day, there will be more or less rain for forty days to come. St Swithin lived just a thousand years ago. He was an eminently pious and learned bishop of Winchester, and priest to King Egbert. He was the deviser and originator of tithes in England. The story runs that, being buried by his own request in the churchyard of the cathedral, the priests a hundred years after felt desirous of giving him greater honour, and commenced the work of translating his remains into the interior. This was on the 15th of July. They were stopped in their work by a heavy fall of rain; neither could they resume their duty next day, for the heavy rain still continued. In short, this rain lasted forty days, by which time the priests became convinced that it was designed to stop them in a work which, though well meant on their part, was ill taken on that of the saint; and they gave up the point. Ever since then, it has been held as a maxim that if there be rain on St Swithin's Day (the 15th of July), there will be rain for the forty ensuing days. In a scientific work on the climate of London, it is acknowledged that 'in a majority of our summers, a showery period, which with some latitude as to time and local circumstances, may be admitted to constitute daily rain for forty days, does come on about the time indicated by this tradition—not that any long space before is often so dry as to mark distinctly its commencement.'

20. *St Margaret's Day.*—This day figures in the Church of England calendar. St Margaret was a holy Italian virgin, martyred in 278. She seems to have been the Christian Lucina: formerly, at Paris, there was a flocking to church on this day of all women who were pregnant, or thought they might be so in the course of the year.

25. *St James the Apostle*, a holiday of the Church of England. In Catholic times, it was customary for the priests on this day to bless the apples. On St James's Day, but according to old style (7th August, new style), oysters appeared in London, and there is a popular notion that he who eats oysters on that day will never want money for the rest of the year.

*Natural History.*—July is the warmest month of the year, the general average temperature being 61 degrees. With us it may be accounted the most important, as its temperature in a good measure regulates the ripening of the crop—that is to say, determines whether it shall be early or late; and in our climate this for the most part may be reckoned a criterion of its value. Flora is in her glory this month. The greatest display of flowers in the whole year takes place in the course of July in our climate. The list includes all the hardy annuals and a great many others. At the same time all our small fruit are in abundance, cherries and strawberries in the beginning being followed by currants, gooseberries, and raspberries, in all their varieties. In the early part of the month barley and oats come into ear, and sometimes in very forward seasons a little barley is cut before the end of July; but very rarely any other kind of grain is ready for the sickle before the middle of August. A great part of the produce of the garden comes to perfection, such as early cabbage, cauliflower, turnips, peas, beans, lettuce, &c. Early potatoes also make their appearance, but are not mature till next month.

AUGUST.

In early Roman times this month was called Sextilis, as being the sixth of the year. The Julian arrangement made it the eighth. It acquired the name *Augustus* in honour of the second of the Cæsars, to whom it had been a fortunate period, he having in it assumed his first consulship, celebrated three triumphs, subdued

Egypt, received the oath of allegiance of the legions that occupied the Janiculum, and terminated the civil wars of Rome. As already mentioned, being dissatisfied with its being a month of thirty days, Augustus took a day from February to make it one of the longer class, like that (July) of his uncle Julius. At the same time, September and November were each deprived of a day, which was added in the one case to October, and in the other to December.

1. *Lammas Day*, called also the *Gule of August*. It is now only remarkable as a day of term for some purposes. It was probably one of the great festival days of our heathen ancestors; and it is worthy of observation that it occurs exactly three months after another of these—Beltane. Cormac, bishop of Cashel in the tenth century, records that in his time four great fires were lighted up on the four great festivals of the Druids—namely, in February, May, August, and November: probably Beltane and Lammas were two of these. Lammas seems to have been held as a day of thanksgiving for the new fruits of the earth. It was observed with bread of new wheat; and there was a custom in some places at no distant period for tenants to be bound to bring in wheat of the new crop to their lord on or before this day. The most rational explanation of the word is that which derives it from the Saxon *Hlaf-mæsse* (loaf-mass, or the loaf-festival), the *f* being in time softened away on account of the difficulty of pronouncing it before *m*. Till the middle of the last century, the shepherds in various parts of Scotland were accustomed to hold festive meetings on Lammas Day on the tops of conspicuous hills, turf towers and benches having been previously constructed for the purpose. The Gule of August is probably from the Celtic *Cul* or *Gul* (a festive anniversary). The early Christian priesthood, finding this word in vogue, Latinised it into Gula, which means throat. This, taken in connection with its being the day of the festival of St Peter ad Vincula (instituted in honour of a relic of St Peter's chains), seems to have suggested to them to make up a story of a daughter of the tribune Quirinus having been cured of a disorder in the throat by kissing the said relic on the day of its festival. And the Celtic *gul* (an anniversary) has thus been the remote cause of a Christian festival being instituted to *Gula* (the throat), and held on the day of St Peter's Chains.

15. *The Assumption of the Blessed Virgin*, a grand festival of the Romish Church, and a day noted in the calendar of the Church of England. It was instituted in 813, to celebrate the ascension of the Virgin into heaven. In Catholic countries, this day is marked by splendid ceremonies and processions.

24. *St Bartholomew's Day*, a holiday of the Church of England. Bartholomew was an apostle, but there is no Scriptural account of his labours or death. The legend of the Romish Church represents him as preaching in the Indies, and concluding his life by being flayed alive by order of a brother of the king of Armenia. In memory of his death, it was customary at our monastic institutions, in the middle ages, to distribute small knives amongst the people. The day has a horrible celebrity in connection with the massacre of the Protestants at Paris in 1572.

*Natural History.*—The mean average heat of this month (60 degrees) approaches so near that of July, that a warm dry August often compensates for a low temperature in the preceding month. In the beginning of August we have often the heaviest rain of the whole year, termed in Scotland the Lammas Flood. July and August, always our warmest, are often our wettest months. Southerly and westerly winds have now the ascendancy, but in the case of very heavy rain the wind usually falls. Harvest, in the average, commences about the middle of this month, but in late seasons not till the very end. The order of ripening of our cereal grains is—barley, wheat, oats. The earliest of our larger fruit begin to ripen this month—apples and pears, but hardly plums. The later and more tender

exotic annuals now come into flower, such as the amarantus, xeranthemum, zinnia, jacobea, China asters, &c.; also the gigantic biennial shepherd's club, which sows itself, and the also gigantic annual sunflower. St John's wort, monkhood, fiox, and others, also flower about this time. This month is likewise the busiest season of the herring fishery, an important branch of industry, which affords lucrative employment to vast numbers of the working population.

SEPTEMBER.

This was the seventh (*septem*) month in the Roman year before the Julian reform of the calendar. The two first syllables of the name are thus readily accounted for; the last, which also figures at the end of the names of the three following months, is an ancient particle of doubtful signification.

1. *St Giles's Day*.—This saint's day figures in the Church of England calendar. A native of Greece, he travelled into France in 715, and became abbot of Nismes. He literally obeyed the Scriptural injunction by selling his patrimony for the benefit of the poor, and on one occasion gave his coat to a sick mendicant, who was cured miraculously by putting it on. St Giles has thus become the patron saint of beggars and cripples. St Giles's Church, Cripplegate, London, and the High Church in Edinburgh, are dedicated to him; and he is the patron saint of the Scottish capital, as far as it can be said to have one.

8. *The Nativity of the Blessed Virgin*, a grand festival of the Romish Church, and still retained in the Church of England calendar. This festival has been held in honour of the Virgin, with matins, masses, homilies, collects, processions, and other ceremonies, for upwards of a thousand years. According to the Catholic writers, a religious contemplative, every year upon the 8th of September, heard most sweet music in heaven, with great rejoicings of angels. Once he asked one of them the cause, and was told that upon that day was celebrated in heaven the nativity of the mother of God. The birthday of the Virgin being thus miraculously communicated to mankind, Pope Servius instituted a festival to hold it in honour.

14. *Holy Rood Day*, or the day of the Exaltation of the Holy Cross, a festival of the Romish Church, still retained in the Church of England calendar. It celebrates the miraculous appearance of a cross in the heavens to the emperor Constantine. The Wednesday, Friday, and Saturday after Holyrood Day, are Ember Days, and the week in which they occur is consequently termed Ember Week.

21. *St Matthew the Apostle*, a festival of the Church of England.

29. *The Festival of St Michael and all the Holy Angels*; shortly, *Michaelmas Day*, a grand festival of the Romish and English Churches. St Michael is singled out for particular mention as being the chief of angels, or archangel. The theological character of Michael is obscure. Suffice it here to quote the remark of Wheatley, in his exposition of the book of Common Prayer, that 'the feast of St Michael and all Angels is observed, that the people may know what benefits are derived from the ministry of angels.'

Michaelmas, besides being one of the quarter-days in England for the payment of rents and wages, has been distinguished from an early period in that and other countries as the time for the annual election of corporation officers, magistrates, and other civil guardians of the peace. It has been suggested that the selection of the day for this purpose might arise from 'the old opinion of tutelary spirits, who have, or are thought to have, the particular charge of certain bodies of men, or districts of country, as also that every man has his guardian angel, who attends him from the cradle to the grave, from the moment of his coming in to the moment of his going out of life.'

It is an ancient and extensively-prevalent custom to have a goose for dinner on Michaelmas Day. Queen

Elizabeth is said to have been eating her Michaelmas goose when she received intelligence of the defeat of the Spanish Armada. Very curious and recondite origins have been assigned to this custom, but it seems to have arisen simply from the goose being in finest condition for the table immediately after it has had the range of the reaped harvest fields.

*Natural History*.—This is often the finest month of the year; yet, as with other portions of our seasons, it is not to be depended on. In temperature (the general average is 55 degrees) it ranks between May and June, yet the first three weeks are often as warm as any part of the summer; but there is usually a sensible falling off in the latter part. In Scotland, the bulk of the harvest work of the season is usually effected during this month. It is likewise the time when large fruit comes to perfection. The flower borders have still a gay appearance, the latest exotic annuals only beginning to flower at this time. The dahlia, a magnificent flower of recent introduction, appears in all its grandeur during September. It has been remarked that at no other period of the year is the house-fly so numerous.

OCTOBER.

As already explained, October has its name from having been the eighth month of the Roman year before the Julian reform of the calendar. In the time of the emperor Domitian it was called Domitianus, in his honour; but after his death that name was abandoned by general consent, from a wish to sink the memory of so execrable a tyrant. The Saxons called October *Wynat-monat* (wine month), from its being the time when wines were annually brought into Germany (none being then made in that country).

2. The festival of the *Holy Angel Guardians* in the Romish Church.

9. The day of *St Dennis*, the patron saint of France. St Dennis was put to death, with some companions, in the year 272, upon an eminence near Paris, since called from that circumstance Montmartre (*Mons Martyrum*). According to the legend, his head had no sooner been cut off, than the body rose, and taking up the head, walked with it two miles. Portraits of the martyred saint, carrying his head in his hand, abound in old prayer-books.

18. The day of *St Luke the Evangelist*, a festival of the Church of England. This day was appointed to be St Luke's festival in the twelfth century.

St Luke was usually represented in the act of writing, with an ox by his side, having wings and large horns. The natural habit of this animal in ruminating upon its food, caused it to be selected as an emblem of meditation appropriate to this evangelist. At Charlton, a village near Blackheath, about eight miles from London, a fair is held on St Luke's Day, and at this fair there was kept up till a very recent period a curious custom, originating evidently in the emblem of St Luke. People came to this fair masked; the men generally wore women's clothes; and many bore horns upon their heads. It was a scene of wild riot and confusion. The booths had horns of various animals, gilt and otherwise, for sale, and even the gingerbread was marked with that figure. 'Horns! horns!' was the universal cry. The gentry used to come in multitudes to see the sports of this occasion. Some fragments of a stained-glass representation of St Luke and his horned companion still exist, we believe, in a window of the parish church.

25. *The Festival of St Crispin and St Crispinian*.—The name of St Crispin is in the Church of England calendar. Crispin and Crispinian are said to have been two Roman youths of good birth, brothers, who, in the third century, went as Christian missionaries to France, and preached for some time at Soissons. In imitation of St Paul, they supported themselves by working at the trade of the shoemaker during the night, while they preached during the day. They were suc-

cessful in converting the people to Christianity, until arrested in their course by Rictius Varus, governor under the emperor Maximian Hercules. Butler, in his 'Lives of the Saints,' says, 'They were victorious over this most inhuman judge by the patience and constancy with which they bore the most cruel torments, and finished their course by the sword about the year 287.' The two young martyrs were of course canonised, and a splendid church was built to their honour at Soissons, in the sixth century. The shoemaker craft throughout the whole Christian world have from an early period regarded Crispin and Crispinian as their patron saints, but particularly the first. They often celebrate the day set apart for these saints in the calendar with processions, in which Crispin, Crispinian, an Indian prince, and some other personages whom tradition has associated with their history, are represented in splendid antique dresses. Sometimes a coronation of Crispin is part of this ceremony, for there is a notion that he was a royal personage; and hence we find the shoemakers, in Scotland at least, assuming for their arms a leather knife surmounted by a crown, and styling themselves 'the royal craft.' Whether they celebrate the day by processions or not, they are sure to distinguish it by giving themselves up for the time to jollity. It is to be hoped, however, for the honour of 'the royal craft,' that there is no foundation for the scandalous censure conveyed against them in the following doggerel couplet:—

'On the twenty-fifth of October,  
There was never a souter sober!'

28. The day of *St Simon and St Jude*, a festival of the English Church. Simon, usually surnamed the Canaanite, remained with the other apostles till after Pentecost: it has been surmised that he visited Britain, and there suffered martyrdom. Jude, otherwise called Thaddeus, and thought to have been a son of Joseph by a former wife, is said to have suffered martyrdom in Persia.

On this day, formerly, it was considered proper to induce winter vestments. It was always expected to be rainy. A character in an old play called the *Roaring Girl*, says, 'As well as I know 'twill rain upon Simon and Jude's day.' In another production of the Elizabethan stage, some one exclaims, 'Now a continual Simon and Jude's rain beat all your feathers as flat down as pancakes.' Perhaps there is some connection between this notion and the emblem assigned to the day in old calendars—namely, a ship, which seems to have been adopted in consideration of Simon and Jude having been fishermen.

*Natural History.*—During this month, the average temperature of which is  $49\frac{1}{2}$  degrees, there are usually decided symptoms of the approach of winter; yet the weather of the month is often of a steady and agreeable character. Bare harvest fields, some of which are in the course of being ploughed for winter wheat, form a conspicuous feature of external nature. The foliage of the trees becomes changed from green into a variety of tints, which gives the woods a beautiful appearance, and is generally admired, although felt to betoken that they are soon to be stripped of their summer honours. The migratory birds assemble, and commence their annual flight to more genial climes—the swallow to the coasts of Africa, the nightingale to the southern shores of the Mediterranean, and the puffin and some others either to Africa or to Spain. Towards the end of the month, if high winds prevail, the trees are a good deal bared. In the gardens less decline is to be remarked. The flower-borders still have a gay appearance; the hollyhock, dahlia, and some other flowers, being yet in good condition. This is the time of the laying up of potatoes. In England, it was the favourite time for brewing, on account of the equable temperature; and *October* is a secondary name for the yeoman's brown beverage. In this month the gossamer has a striking appearance, floating like an aerial veil over the fields, and meshing the passing traveller.

November obtained its name from being the ninth (*novem*) month of the Roman year, before the reform effected by Cæsar. Our Saxon ancestors called it *wistmonat* (wind month).

1. *All Saints' Day*, a festival of the Romish and English Churches—otherwise called *All Hallow Day*. The evening of the 31st October is called *All Hallow Even*, or *Hallow E'en*, as being the vigil or eve of *All Hallow Day*. *Hallow-tide* is a comprehensive name for both days. The Romish Church designed this day to be held in honour of all those saints who had not particular days appointed for them.

It does not appear that *All Saints' day*, or its *Eve*, was ever marked by very particular observance in the Catholic Church. Nevertheless, there is scarcely any time more distinguished by the common people throughout the British islands than *All Hallow Eve* or *Hallowe'en*. This is probably owing to the fact of *November 1st* having been one of the four great festivals of our Pagan ancestors. The 1st of February, the 1st of May, and the 1st of August, were the other three; the ancient names of the two latter are still in vogue—*Beltane* and *Lammas*. These four days were celebrated by the kindling of fires in conspicuous places, and performing certain ceremonies. The fires of *Beltane* and *Lammas* have already been spoken of; it is probable that those of the February festival are kept up in the *Candlemas blaze*, with a slight change of day. Fires were kindled in Wales, Ireland, the Scottish Highlands, and even in England, on the 1st of November, till a very recent period; and the custom may still be kept up in some remote places.

Pennant states as follows:—'In North Wales there is a custom upon *All Saints' Eve* of making a great fire called *Coel Coeth*. Every family, about an hour in the night, makes a great bonfire in the most conspicuous place near the house, and when it is almost extinguished, every one throws a white stone into the ashes, having first marked it; then having said their prayers turning round the fire, they go to bed. In the morning, as soon as they are up, they come to search out the stones, and if any of them are found wanting, they have a notion that the person who threw it in will die before he sees another *All Hallow Eve*.' The Welsh also practise many of those rites for divining the future which are so prevalent on *Hallowe'en* in other parts of the United Kingdom. It is mentioned by another writer that they dance round and jump through the bonfires, and at the conclusion always run away, 'to escape the black short-tailed sow.' Vallancey states that the Irish have now generally substituted a candle illumination for the fire of the 1st of November.

The Rev. Mr Shaw, in his 'History of Moray,' written in the latter part of the last century, speaks of the *Hallow Eve* fire being still kindled in Buchan. In the 'Statistical Account of Scotland,' published at the close of the century, the same fire is spoken of as kept up in various parts of the Highlands. In the parish of Callendar, for instance, 'On *All Saints' Eve*, they set up bonfires in every village. When the bonfire is consumed, the ashes are carefully collected in the form of a circle. There is a stone put in, near the circumference, for every person of the several families interested in the bonfire; and whatever stone is moved out of its place, or injured, before the next morning, the person represented by that stone is devoted, or *fey*, and is supposed not to live twelve months from that day.' How strange thus to find a superstitious custom of this nature existing in a form so nearly identical in Wales and Perthshire.

Several writers in the *Gentleman's Magazine*, in the latter part of the last century, speak of *Hallow Eve* fires being still kindled in various parts of England, chiefly by persons of the Catholic persuasion. The practice seems to have been to carry about a quantity of burning stuff, under the name of *tinley* or *tindle*.

## KEY TO THE CALENDAR.

These ceremonies appear to be amongst the earliest connected with the 1st of November. They are, or have recently been, everywhere prevalent throughout these islands. As they are obviously of a Pagan character, we conclude that the notability of this season is of older date than the introduction of Christianity, and that its character as All Saints' Day has comparatively little affected the popular mind.

We have notices from both Perthshire and Ireland of the 1st of November being partly regarded as the proper time for returning thanks for the realised fruits of the earth. The Irish, in this regard, called it *La Mas Ubbal*—that is, the day of the apple fruit—and celebrated it with a drink or mess composed of bruised roasted apples amongst ale or milk. This drink in time acquired the strange appellation of *lamb's wool*, a stupid corruption apparently of the name of the day in the Celtic language.

Ringling of bells was one of the modes of celebrating Hallowmas in England in the days of our ancestors. It was a Roman Catholic practice, being designed in some way to favour the souls of departed Christians. For this reason Queen Elizabeth prohibited it.

It was also a custom of our Catholic forefathers to have a cake baked on this eve for every member of the family, as a *soul mass cake* or *soul cake*. It was composed of oatmeal, and seeded; and pasties and furnety were incidental to the same evening. In families of good condition, a quantity were baked and set up on a board, like the shew-bread in old pictures in the Bible, to be given to visitors, or distributed amongst the poor. There was a rhyme for the occasion—'A soul cake! a soul cake! Have mercy on all Christian souls for a soul cake!' People went from parish to parish *a-souling*, as they called it—that is, begging in a kind of chant for soul-cakes, or anything to make them merry on this eve. It is very curious to find that a century and a half ago the inhabitants of St Kilda, so far removed from all other parts of Britain, had a custom of baking a large triangular cake, furrowed on the edges, on All Saints' Night.

Essentially connected with all these customs are those better known ones which Burns has so well and so faithfully described in his poem of *Hallowe'en*. All over the British islands, the festive and fortune-telling practices of this evening are very nearly the same. As some proof of this, passages from an English, Irish, and Scottish poet may be presented side by side:—

Two hazel-nuts I threw into the flame,  
And to each nut I gave a sweetheart's name:  
This with the loudest bounce me sore amazed,  
That in a flame of brightest colour blazed;  
As blazed the nut, so may thy passion grow,  
For 'twas thy nut that did so brightly glow!

—*The Spell*, by Gay.

These glowing nuts are emblems true  
Of what in human life we view;  
The ill-matched couple fret and fume,  
And thus in strife themselves consume;  
Or from each other wildly start,  
And with a noise for ever part.  
But see the happy, happy pair,  
Of genuine love and truth sincere:  
With mutual fondness, while they burn,  
Still to each other kindly turn;  
And as the vital sparks decay,  
Together gently sink away:  
Till life's fierce ordeal being past,  
Their mingled ashes rest at last.

—*Nuts-Burning*, All Hallowe've, by Charles Graydon.

Jean slips in twa wi' tentie ee,  
Wha 'twas she wadna tell;  
But this is Jock and this is me,  
She says in to hersel':  
He bleezed owre her, and she owre him,  
As they wad ne'er mair part,  
Till suff' he started up the lum,  
And Jean had e'en a sair heart  
To see't that night.

—*Hallowe'en*, by Burns.

Nuts, besides being thus used for divination, are cracked and eaten; and hence, in the north of England, All Hallow Eve is often called *Nut-crack Night*. Apples are also extensively eaten, this consumpt of fruit having probably some reference to the heathen character of the day, as that of thanksgiving for the produce of the season. The fortune-telling customs described by Burns, besides the above, are—for the girls to pull stalks from a corn-stack, and ascertain, from the presence or absence of the top pickle, an interesting point in their moral history—for a solitary female to go to a kiln, and throwing a blue clue into the pot to wind it, expecting that ere finished it will be held back, when, by inquiring who holds, a response will be obtained disclosing the name of the future husband—to eat an apple at a looking-glass, expecting to see a vision of the future husband peeping over the shoulder—to sow hemp-seed in the yard, saying, 'Hemp-seed, I saw thee, hemp-seed, I saw thee, and her that is to be my true love come after me and draw thee,' expecting that, on looking over the shoulder, a vision will be obtained of the future spouse in the act of pulling grown hemp—to win three wechts o' naething in the barn, expecting to see a like vision—to fathom a barley-stack thrice, expecting at the last to embrace your mistress—to dip a shirt sleeve in a rivulet at the meeting point of the lands of three proprietors, and then hang it by the fire to dry, trusting to see such a visionary person come in and turn the other side—to pull stalks of deceased cabbages blindfolded, without choice, and augur, from their straightness or crookedness, the figure of the future spouse, from the earth which clings to the root the fortune she will bring, and from the taste of the heart her temper—finally, to set three dishes on the floor, one empty, one with clean, and one with foul water, and cause the company to approach them blindfolded and dip in a hand; when he who dips in the empty one is expected to remain unmarried, he who dips in the foul one to marry to a widow, and he who dips in the clean one to marry a female not hitherto married. The whole of these rites are as familiar to the Welsh, Irish, and Northumbrian, as to the Ayrshire peasantry. Many of them are also practised in England on St John's Eve, the 23d of June.

Hallowe'en is still observed, but the more daring rites are generally given up. Meetings of young persons take place, and a plentiful store of nuts and apples being provided, a few simple amusements are practised. The experiment of the burning nuts, to test the durability of love or friendship, is still a favourite. Ducking for apples is another. A tub being provided, nearly full of water, and the fruit thrown in, the young people endeavour to seize an apple with their teeth—a task of much more difficulty than might be supposed, and which generally puts the dress and tresses of fair experimentalists into considerable disorder. The baffled efforts of the various parties raise of course shouts of laughter. Or a cross stick is suspended by a string from the ceiling, with a short burning candle on one end and an apple on the other. While it swings rapidly round, lads and lasses, with their hands tied, endeavour to catch the apple with their teeth, but generally suffer a good deal from the candle before they succeed in their object. Here, also, failure is a source of infinite amusement. It is rather remarkable that Burns has not introduced into his poem any notice of these sports, which, like the others, are prevalent over the whole of her Majesty's home dominions. It may not be out of place here to remark, that the jest of the apple and candle is nearly the same as that of the quintain, a favourite sport of our ancestors, commonly practised in summer. The quintain was a heroic figure of wood, on a vertical pivot, used as a butt for the practice of tilting. In this case it had a cross board, one end of which was broad, while the other was furnished with a heavy bag of sand. The trick was, to come tilt against the broad end, and escape receiving a knock-down blow from the sand-bag.

2. *All Souls' Day*, or the Commemoration of the Faith-

*ful Departed.*—A very solemn festival of the Romish Church, which has masses and ceremonies appropriate to the occasion, designed in favour of the souls of all the dead. 'Odillon, abbot of Cluny, in the ninth century, first enjoined the ceremony of praying for the dead on this day in his own monastery; and the like practice was partially adopted by other religious houses until the year 998, when it was established as a general festival throughout the western churches. To mark the pre-eminent importance of this festival, if it happened on a Sunday, it was not postponed to the Monday, as was the case with other such solemnities, but kept on the Saturday, in order that the church might the sooner aid the suffering souls; and that the dead might have every benefit from the pious exertions of the living, the remembrance of this ordinance was kept up by persons dressed in black, who went round the different towns, ringing a loud and dismal-toned bell at the corner of each street, every Sunday evening during the month, and calling upon the inhabitants to remember the deceased suffering the expiatory flames of Purgatory, and to join in prayers for the repose of their souls.'—*Brady's Clavis Calendaria.*

5. The anniversary of the discovery of the Gunpowder Plot in 1605, and of the landing of King William III. in 1688; observed in the British dominions as a holiday, and celebrated by the Church of England by a form of prayer with thanksgiving. There is also a popular celebration of this day. From an early hour, the boys go about collecting materials for a bonfire, or money wherewith to purchase them. In some, perhaps most places, they carried with them a frightful figure composed of an old suit of clothes stuffed with straw, to represent Guy Fawkes. They called on the passengers and householders to 'remember Guy,' or shouted some balderdash rhymes. In the evening the bonfire is lighted, with Guy Fawkes in the middle of it, amidst tumultuous merriment. The firing of guns as a token of rejoicing, we are glad to say, is now discontinued on this day, and we trust the other absurd usages will soon likewise disappear.

11. *St Martin's Day, or Martinmas*, in the Church of England calendar. Popularly, this is one of the most remarkable days of the year, especially in Scotland, where Whitsunday and *Martinmas* are the two great terms for leases and engagement of servants, the latter being that at which the occupation of farms usually commences. Formerly, it was a quarterly term day in England: a payment of corn at *Martinmas* occurs in the Doomsday Survey. On the continent, from an early age, the day has been distinguished convivially; and this apparently for two reasons—namely, that now the people first tasted the wines of the season, and killed the animals required to be salted for their winter provisions. The entrails of these animals, prepared as sausages, or blood-puddings, became the subject of an immediate feast, while the rest of the meat was salted and set aside. In some countries, also, the goose, which is elsewhere enjoyed at *Michaelmas*, was now presented. The killing of beeves at *Martinmas* for winter provision was formerly universal in northern Europe, in consequence of there being no means of keeping them alive in winter; since the improvement of husbandry in some countries, the custom has been given up, and fresh meat used all the year round. The feasting upon the entrails was equally universal. So much was all this associated with *Martinmas*, that in Scotland a beeve killed at that time was called a *mart*, or *mairt*. In the old book of laws attributed (erroneously) to David I. of Scotland, it is provided that 'the fleshours sall serve the burgessis all the time of the slaughter of *Mairts*.' In Northumberland, also, a *Martinmas* bullock is called a *mart*. Tusser, in his curious metrical treatise on husbandry, written in the time of Henry VIII., says—

When Easter comes, who knows not than  
That veal and bacon is the man?  
And *Martinmas* beef doth bear good tack,  
When country folks do dainties lack.

Bishop Hall, in his '*Satires*,' written in the time of James I., mentions

— Dried filitches of some smoked beeve,  
Hang'd on a withren wythe since *Martin's* eve.

It appears that the contents of the puddings, as made in England, were composed of blood, suet, and groats; and there was an enigmatical proverb thence arising, that 'blood without groats was nothing,' meaning that birth without fortune was of little value. Down to near the end of the last century there was not a family above the poorest condition in the rural districts of Scotland which had not a *mart*, or a share in one, and salted meat was the only food of the kind used in winter; now, there is no such practice known.

*Martin*, in whose honour this festival was at first instituted, is said to have been born in Lower Hungary about 316, and to have originally been a soldier. After a number of miraculous adventures, he settled as a hermit in the hollow of a rock near Tours in the south of France, where he was greatly venerated. He died bishop of Tours in 397. When a few fine days occurred about this time of the year, they were called *St Martin's summer*.

23. *St Clement's Day*, in the Church of England calendar. Clement is spoken of by St Paul as one of his fellow-labourers. Monkish imagination has supplied him with a history and a martyrdom. He is said to have been thrown into the sea with an anchor fixed about his neck. An anchor is therefore assigned to him as an emblem: of this the metropolis presents a conspicuous memorial in the anchor which forms the vane of the church of St Clement Danes, in the Strand. St Clement is held as the patron saint of the blacksmiths. It was formerly customary for boys, and the lower class of people generally, to go about on this day begging for liquor, wherewith they made a regale at night. Hence, in a certain class of old almanacs, the day was signified by the figure of a pot.

29. This is one of the days on which *Advent* may commence. *Advent* (literally the Coming) is a term applied from an early period of ecclesiastical history to the four weeks preceding Christmas, which were observed with penance and devotion, in reference to the approaching birth of Christ. There are four Sundays in *Advent*, the first of which is always the nearest Sunday to St Andrew's Day (November 30).

30. *St Andrew's Day*.—The festival day of this saint is retained in the Church of England calendar. St Andrew was one of the apostles. His history, as related by the Catholic writers, represent him as martyred in the year 66 at Patre in Greece, upon a cross of the form of the letter X, which accordingly is still recognised as St Andrew's Cross. A supposed relic of this cross, carried to Brussels in the middle ages, caused its figure to be adopted as a badge for the knights of the Golden Fleece. Some relics of the apostle himself are said to have been carried by a Greek devotee named St Regulus, to Scotland, where they were placed in a church built at a place which subsequently became distinguished by the name of St Andrews. St Andrews became the seat of the Scottish primacy; and from this cause probably it was that St Andrew was in time considered as the patron saint of Scotland. In that country, however, there is scarcely any observance of this day in any manner; it is only when Scotsmen are abroad, and have occasion to select a day for an annual convivial meeting, that St Andrew's Day comes into notice. There used to be a procession of Scotsmen on this day in London, with singed sheeps' heads borne before them. It is remarkable that St Andrew is also a tutelary saint of the Russians, probably in consequence of the Greek locality of his martyrdom. There is an ancient and widely-prevalent custom connected with St Andrew's Day, to which Luther has adverted. Maidens, on the eve of this day, stripped themselves, and sought to learn what sort of husbands they were to have by praying in these terms—'Oh, St Andrew, cause that I obtain a good pious husband; to-night show me the figure of the man who will take me to wife.'

## KEY TO THE CALENDAR.

**Natural History.**—In this month the business of vegetation experiences its death. The trees are now thoroughly stripped of their foliage. It is reputed as a gloomy month; but the temperature is sometimes agreeable in the earlier part of it, and its average for the whole term is 43 degrees. A considerable number of plants remain in flower throughout November. The gloom of the month is said to have a depressing effect on the spirits of the English nation; let those who are liable to such influences lay to heart the following remarks of Johnson in the 'Idler':—'The distinction of seasons is produced only by imagination acting upon luxury. To temperance every day is bright, and every hour is propitious to diligence. He that resolutely excites his faculties, or exerts his virtues, will soon make himself superior to the seasons, and may set at defiance the morning mist and the evening damp, the blasts of the east and the clouds of the south. Instead of looking for spring with anxious and caring mind, enjoy the present day; there are pleasures even in November.'

### DECEMBER.

So called as being originally the *tenth* of the Roman year. Our Anglo-Saxon ancestors called December *winta monath*—that is, winter month; but after becoming acquainted with Christianity, this name was changed into *haligh monath*, or holy month, with reference to the celebration of the nativity on its twenty-fifth day.

6. *St Nicholas's Day.*—Retained in the Church of England calendar. St Nicholas was Archbishop of Myra, in Greece, A. D. 342. He is regarded as the patron saint of children and of mariners, probably in consequence of his benevolent zeal in the protection of orphans and stranded seamen. Churches built near the sea are in many instances dedicated to St Nicholas. He is also said to have shown much kind interest in the fate of young women, sometimes secretly throwing purses into the chamber-windows of those who lacked dowries. Hence has arisen a custom prevalent over a large part of the Christian world. On his eve, presents are hid in the shoes of those to whom any one wishes to give a pleasing surprise; and these, being found in the morning, are jocularly said to be gifts from St Nicholas.

St Nicholas is also considered as the tutelary saint of scholars, or clerks, and of robbers. The fraternity of parish-clerks have thought themselves entitled by their name to adopt him as their patron. How robbers should have come to be called St Nicholas's clerks, or St Nicholas's knights, it is not easy to see, unless it were from the coincidence of his name with one of the slang appellations of the devil.

Throughout the middle ages, there was a universal custom of electing a kind of mock bishop on St Nicholas's Day. A boy, possibly taken from amongst the choristers, was chosen by his associates as bishop, arrayed in suitable vestments, and indued with appropriate powers, which he enjoyed for some days. The infant prelate was led along in a gay procession, blessing the grinning multitude as he went, and he was even allowed to sing mass and to mount the pulpit and preach. Edward I., in his way to Scotland in 1299, heard vespers by a boy bishop at the chapel of Heton, near Newcastle. The boy bishop at Salisbury is said to have had the power of disposing of any prebends that fell vacant during his term of office; and one who died at that time had a monument in the cathedral, representing him in his episcopal robes. Mr Warton is of opinion that we see some faint traces of the rise of dramatic entertainments in the strange mummeries connected with the election of the Boy Bishop.

8. *The Conception of the Blessed Virgin* in the Romish and English calendars.

11. The fourteen days from this to Christmas Eve were called the *Halcyon Days*, and supposed to be, in their calm and tranquil character, an exception from the season. The term, which is now a regular adjective in our language, is derived from the bird, kingfisher or halcyon, which, from the days of Aristotle at

least, has been the subject of a curious superstition. The ancients supposed that it built its nest on the ocean, and brought forth its young at the winter solstice. To account for the preservation of the nest and young amidst the severity of the season, they imagined that the bird had a power of lulling the raging of the waves during the period of incubation; and this power was believed to reside in its song.

13. *St Lucia's Day.*—Retained in the Church of England calendar. St Lucia was a young lady of Syracuse, who obtained a high character for a devout and charitable life, and died in the year 304. The last of the four series of Ember Days commences on the Wednesday following this festival.

16. *O Sapientia.*—This day is so marked in the church calendar, probably from an anthem sung on this day in the Romish Church beginning, 'O sapientia quæ ex ore altissimi prodidisti,' &c.

21. *St Thomas the Apostle*, a festival of the English Church. It was customary for women to go *a-gooding* on St Thomas's Day; that is, they went about begging money, and presenting in return sprigs of palm, and bunches of primroses, probably with a view to the decoration of their houses against Christmas.

25. *Christmas Day*, observed from an early period as the nativity of our Lord, and celebrated not only by the religious ceremonies from which the name of the day is partly taken, but by popular festivities of the most joyful kind. In England, Christmas is held by the church as a solemn festival, and distinguished by the complete cessation of business—an honour paid to no other day besides Good Friday. But within the last hundred years, the festivities once appropriate to the day have much fallen off. These at one time lasted with more or less brilliancy till Candlemas, and with great spirit till Twelfth Day; but now a meeting in the evening, little different from a common dinner party, though sure to be marked by a roast and plum-pudding, and pretty generally followed by a game at cards, is all that distinguishes Christmas in most families.

In former times the celebration of Christmas began in the latter part of the previous day—Christmas Eve. The house was first decked with holly, ivy, and other evergreens. Candles of an uncommon size were then lighted, under the name of Christmas Candles; an enormous log, called the Yule Clog, or Christmas Block, was laid upon the fire: the people sat round, regaling themselves with beer. In the course of the night, small parties of songsters went about from house to house, or through the streets, singing what were called Christmas Carols—simple popular ditties, full of joyful allusions to the great gift from God to man in the Redeemer. A mass was commenced in the churches at midnight, a custom still kept up in the Catholic Church. At one period, the people had a custom of wassailing the fruit-trees on this evening; that is, they took a wassail bowl, threw a toast from it to the tree, and sung a song, expecting thus to secure a good crop next season. It was thought that, during the night, all water was for a short time changed into wine, and that bread baked on this eve would never become mouldy. These notions are essentially foolish; but as they are all well-meant adorations of the simple spirit of the people, they should not be hastily condemned.

The carols were more generally sung in the morning of Christmas Day. A contributor to the 'Gentleman's Magazine,' in 1811, describing the manner in which Christmas is celebrated in the North Riding of Yorkshire, says—'About six o'clock on Christmas Day I was awakened by a sweet singing under my window; surprised at a visit so early and unexpected, I arose, and looking out of the window, I beheld six young women and four men welcoming with sweet music the blessed morn.' It may scarcely be imagined how delightfully at such a moment would fall upon the half-slumbering ear such strains as the following:—

God rest you, merry gentlemen,  
Let nothing you dismay,

For Jesus Christ our Saviour  
Was born upon this day,  
To save us all from Satan's power,  
When we were gone astray.  
  
Oh tidings of comfort and joy,  
For Jesus Christ our Saviour  
Was born on Christmas Day.

In Bethlehem in Jewry  
This blessed babe was born,  
And laid upon a manger,  
Upon this blessed morn;  
The which his mother Mary  
Nothing did take in scorn.  
Oh tidings, &c.

Christmas carols are amongst the oldest of English songs. A collection of them was printed by Wynkyn de Worde in 1521. They are still printed on single sheets, which are sold by chapmen or dealers in cheap literature. There is also more than one modern collection of these curious productions of modern ages.

The religious service of Christmas Day receives but a small share of attention from old writers. In fact, the day was chiefly distinguished by the popular festivities. Its grand feature was a feast, of great abundance, and at which a few particular dishes regularly appeared, above all, plum-porridge and mince-pie. In every great hall, whether of a man of rank or of a great corporation, there was a boar's head ushered in by minstrelsy. It was customary for the rich and noble to treat their humble dependents, and to meet with them on terms of equality, as considering that all men are regarded alike by the religion of him whose natal day they are celebrating. A sort of license prevailed. A branch of the mistletoe being hung up in the hall, or over the doorway, the youths were understood to have a right to kiss any maiden whom they could inveigle under it. At York, the freedom of the time was so extreme, that there were regular proclamations allowing women of evil repute and gamblers to come to the city and walk about openly for a certain number of days. It was also customary to elect a person as *Lord of Misrule*, who went about taking the lead in every kind of extravagant sport and merriment which the wit of man could devise. The election and functions of this personage were perhaps the most singular part of the festival. According to Stow, 'at the feast of Christmas, there was in the king's house, wherever he lodged, a Lord of Misrule, or Master of merry Disports, and the like had ye in the house of every Nobleman of honour or good worship, were he spiritual or temporal. The Mayor of London, and either of the Sheriffs, had their several Lords of Misrule, ever contending, without quarrel or offence, who should make the rarest pastime to delight the beholders. These lords, beginning their rule at Allhallond Eve, continued the same till the morrow after the Feast of the Purification, commonly called Candlemas Day: in which space there were fine and subtle disguisings, masks, and mummeries, with playing at Cards for Counters, Nayles, and Points in every House, more for pastimes than for gaine.'

The management of the plays usually acted at Christmas in the halls of colleges and law societies, fell to the care of the Lord of Misrule. The particular functionary elected in the inns of court in London, after exercising all the duties and going through the parade of royalty for a fortnight, at an expense of a couple of thousand pounds, was knighted at Whitehall by the real sovereign of the land.

In Scotland, before the Reformation, the religious houses had a similar officer for the Christmas revels, called the *Abbot of Unreason*, whose particular functions are graphically portrayed by Scott in his novel of 'The Abbot.' The custom was suppressed by statute in 1555.

26. *St Stephen's Day*, observed as a festival of the Church of England. There was formerly a widely-prevalent dogma that it was good to bleed horses about

this time of the year, and *St Stephen's Day* was that chosen by most people for the purpose. On this day, also, blessings were implored upon pastures.

27. *St John the Evangelist's Day*, observed as a festival by the Church of England. Because John drank poison, without dying in consequence, it was supposed that those who put their trust in him were safe from all injury from that cause.

28. *Childermas*, or *Holy Innocent's Day*, observed by the Church of Rome with masses for the children killed by Herod. It was considered unlucky to marry, or to begin any work, on Childermas Day. The learned Gregory says, 'It hath been a custom, and yet is elsewhere, to whip up the children upon Innocent's Day morning, that the memory of Herod's murder might stick the closer, and in a moderate proportion to act over the "crueltie again in kinde."'

31. The last day of the year is called in Scotland *Hogmanay*, a word which has fruitlessly exercised the wits of the etymologists. The Scottish people, overlooking Christmas in obedience to the behests of their religious teachers, have transferred the merriment of the season to Hogmanay and New Year's Day, which they accordingly abandon to all kinds of festivity. Handseil Monday, or the first Monday of the year, is also an occasion of festivity. On Hogmanay, the children in small towns perambulate amongst the neighbours of the better class, crying at their doors, 'Hogmanay!' or sometimes the following rhyme:—

Hogmanay, trololay,  
Gie's of your white bread and none of your gray;

in obedience to which call, they are served each with an oaten cake. In the evening, there are merry makings, which are always prolonged to twelve o'clock, which has no sooner struck than all start up excitedly, and wish each other a happy new year. Small venturous parties take a kettle with hot ale posset, called 'a het pint,' and go to the houses of their friends, to wish them a happy new year. Whoever comes first, is called in that house 'the First Foot,' and it is deemed necessary on such occasions to offer the inmates both a piece of cake and a sip from the posset kettle, otherwise they would not be lucky throughout the year. This is called 'First-Footing.' Next day, all people go about among all other people's houses; presents are given amongst relations; and dinner-parties close the evening. Formerly, the first Monday of the year was also much observed as a festive day, and time for giving presents, from which latter circumstance it was called *Handseil Monday*. The Handseil Monday, old style, is still, in some rural districts, the chief feast day of the season. On the evenings of Christmas, Hogmanay, New Year's Day, and Handseil Monday, parties of young men and boys went about disguised in old shirts and paper vizards, singing at the various houses for a small guerdon. These *guizaris*, as they were called, also acted a rustic kind of drama, in which the adventures of two rival knights, and the feats of a doctor, were conspicuous. Almost everywhere in Scotland the festive and frolicsome observances of the New Year tide have very much declined.

*Natural History*.—December is the darkest, but not the coldest month of the year: the general average temperature is 40 degrees. The deciduous trees are now completely stripped of their foliage, and the ground often shows a snowy covering, although it is rarely that there is much strong ice in December. Amidst the general desolation, the pines and other evergreens form an agreeable resting-place for the eye. The rose also continues to blow during this month. Formerly, the Glastonbury thorn was a great wonder in England, being supposed to blow regularly on Christmas Day. The monks of the abbey there represented it as the staff of Joseph of Arimathea, which, being inserted by him in the ground, had miraculously sprouted out into a living tree. But it is now ascertained to have been only a member of a certain species of thorn well known in the East for blowing in the depth of winter.

## THE PRIVATE DUTIES OF LIFE.

THE temporal duties enjoined on rational beings may be thus classed:—1. Duties which one owes to himself.—2. Duties which arise from domestic relations.—3. Duties which arise in the communities of which each one is peculiarly a member.—4. Duties which arise from the political relations of society.—5. Duties which arise between individuals who are of different nations. We propose in the meantime to treat of those duties which a rational being may be said to owe to himself, or, as they are generally termed, PRIVATE DUTIES.

### LIFE AS A WHOLE.

Life is a succession of parts—infancy, youth, manhood, maturity, decline, old age, and death. What man becomes depends in part on his genealogy: as his infancy is, so will be his youth; as his youth is, so will be his manhood; as his manhood is, so will be his maturity; as maturity is, so will be decline; as decline is, so will be old age. If youth be passed in idleness, ignorance, folly, and crime, how can one hold his way in the world, side by side with the intelligent, the worthy, and the virtuous! If manhood has been passed in low pursuits, in rooting in the heart evil propensities, in wasting natural vigour, what awaits one in old age but poverty, pity, and contempt! If infancy be devoted to the reasonable expansion of the physical and intellectual powers—if knowledge of duty be acquired, and be rightly used, will not manhood be worthy, maturity respectable, decline honoured, and old age venerable! Life, then, must be taken as one event, made up of many successive ones. On these unquestionable truths we found all that is worthy of notice in the following pages.

### PURPOSES OF LIFE.

We believe that human life, rightly understood, and rightly used, is a beneficent gift; and that it can be so understood and used. It is irreconcilable to reason that man was sent into this world only to suffer and to mourn; it is from his own ignorance, folly, or error that he does so. He is capable of informing himself; the means of doing this are within his power. If he were truly informed, he would not have to weep over his follies and errors. It is not pretended that every one can escape at once from a benighted condition, and break into the region of reason and good sense. But it is most clear, from what is well known to have happened in the world, that each generation may improve upon its preceding one; and that each individual, in every successive period of time, may better know the true path, from perceiving how others have gone before him. There can be no miracle in this. It will, at best, be a slow progress: and the wisdom arrived at in one age must command the respect of succeeding ones, and receive from them the melioration which they can contribute. We understand nothing of what is called the perfectibility of human nature; but we understand this, that if human nature can be made to know wherein its greatest good consists, it may be presumed that this good will be sought after and obtained. Man was created on this principle, he acts on this principle, although he is seen so frequently to make the most deplorable and distressing mistakes. If it be not admitted that mankind will always strive to obtain whatsoever seems to them good, and strive to avoid whatsoever seems to them evil, their moral teaching and training is in vain. If this principle be admitted, the sole inquiry is—what then is good? and what is evil?

### INFANCY.

Every human being comes into the world with physical and intellectual qualities, propensities, and aptitudes, which distinguish him as much from all other

beings, as he differs from them in figure and appearance. As society is a consequence of the Creator's will, as the proper divisions of labour are a necessary consequence of society, it is not irrational to suppose that individuals are born with adaptation to labour in some departments, and not in others. In the early stages of life these qualities are sometimes developed, whether they happen to be understood or not. But almost immediately after gaining some hold on life, all human beings become subject to the incidents which tend to strengthen original qualities, or to obscure or stop their progress, and even to suppress them, and engraft on the original stock those which are entirely different. It would be unjust to make infancy responsible for the evils and errors which arise in this manner; but certainly those who have the guidance of infancy are responsible, and will be held to be so. Children have a right to complain, and society has a right to complain, if duties to children be neglected; and it is needless to remark that there is another and inevitable accountability of a far more serious character. We shall have occasion to remark on the very onerous and important duties of those who, according to the order of natural and necessary law, are intrusted with forming and giving effect to natural qualities. This matter, however, properly belongs to another place.

### YOUTH.

We come now to a period when accountability begins, in all the relations which were placed in the division of duties. If it be asked at what age this is to be fixed, we answer, that the good sense of judicial law recognises that a child may be a witness in solemn judicial proceedings, when inquiries addressed to him are so answered as to make it certain that he understands the nature and the obligation of an oath. This may be at the age of ten or twelve years. But the perception of right and wrong, and the sense of duty, begin at an earlier age. There certainly are children of the age of eight years who have a very clear sense of moral propriety; and very many who, between that age and twelve, can discern and reason on right and wrong, and arrive at a very sound judgment. We shall presume that all into whose hands this sheet may fall will be fully capable of comprehending its purpose, and of judging of its fitness to be useful to them. We must assume, then, that we are speaking to those who are willing to be instructed in serious things, and that they will not reject instruction from any source, however unpretending it may be, if it come to them in a manner which they can reconcile with their own reason, and with their own duty to themselves. Young persons think that they can see for themselves, and that they need not to be told what others have seen. But let us reduce this to common sense. Suppose a person to be under the necessity of going from the place in which he has lived, and which is familiar to him, to a far distant place. Let it be supposed that the road he must travel is crossed by many roads, and that he is frequently to find himself at points where several roads are seen, either one of which, so far as he can discern, may be the right one. Will it be of use to him to have been told, before he departs, which of these many roads to take? Will it help him onward to his destination, when he is bewildered, and unable to decide for himself, to find some one who can assure him of the right course? Life is a journey. Every step we take in it brings us to something new, something unexpected, and perhaps entirely different from that which was looked for. Those who have gone through it before us have left us their instructions in what manner it is to be undertaken and accomplished. They tell us of their own troubles and

difficulties; they warn us how to avoid the like in our own journey. Which is wisest—to listen to them, and weigh the worth of their warning, or to push on heedlessly, and take the consequences?

## HEALTH—FOOD.

We suppose that every child of the ages last spoken of can form some opinion of the value of health. Most of them have suffered more or less by that time. They are now old enough to consider the purposes for which life has been given to them. They then feel that the purpose is to be pleased and gratified; to want and to have; and that restraint is disagreeable. But let them remember that life is a whole; that though all of them will not, yet some of them will, attain to its longest duration, and that it is wholly uncertain to whom that lot will fall. Long life may depend, and often does depend, on what children do, or omit, at an early age. Among the first gratifications which are looked for at this period, is the indulgence of the appetite for food. Here comes in a rigid law of the Creator. It cannot be broken without consequent suffering, nor repeatedly broken without impairing, and perhaps destroying, the material frame which has been described as so fearfully and wonderfully made. To require of that delicate machinery, on which the action of life depends, that which it is not qualified to do, and which it cannot do—to force it to do that which is offensive to it—and to make this requisition habitually—is a sin against natural law. Its punishments are well known. The restless sleep, the heavy head, the many sensations of uneasiness, the positive pain, the disgusting remedies, are the punishments which follow. They are not all. Nature loses its charms, companions their interest, duties become irksome, the mind hates its labour, penalties are incurred, parents or teachers are regarded with displeasure. These are the fruits of momentary and improper gratification of the appetites. On the other hand, there is a law of nature that food shall be grateful. It is required to supply the daily waste—to continue life. If there were not a craving want, we should take food as a mere necessary duty. It is kindly made to be a pleasure, and, like every other pleasure, it is to be used, and not abused. Thus, by ignorant or willful pursuit of pleasure, we violate a law which brings with its just punishment not only the loss of the like pleasure for a time to come, but also pain and suffering from indispensable remedies. When children are sick, they are subjects of tenderness and pity; but in most instances they rather deserve to be punished, for they have broken a law wilfully, since they have disregarded their own experience. As to kinds or *quality* of food, nature is not unreasonably nice about this: that which it more frequently complains of is *quantity*.

## CLEANLINESS.

This is not a mere matter of decency. It is one of the positive commands arising from the constituted order of things. Be it remembered that everything that lives, vegetable or animal, is wasting while life continues; and that all which is sent forth through the millions of openings by the skin, has run its round, and is lifeless; and that more than half of all the food taken comes forth in this manner. (See *PRESERVATION OF HEALTH*, Vol. I.) If perspiration, sensible and insensible, be permitted to rest on the skin, and stop the way of that which is coming, nature is offended, and will show that she is so. Such neglect is one of the causes of disease. This fact was probably well known to Eastern nations, since it was part of their religious duty to cleanse the skin. These nations were ignorant of the modern comfort of wearing a garment next the skin which can be frequently changed. The absence of this comfort was one of the causes of those dreadful diseases of which we read, and which are now unknown among Christian nations. There are classes of labourers and mechanics whose health would be preserved, and their lives prolonged, if they knew how much depended

on periodical cleansing. It may be said that there is a connection between cleanliness and moral feeling. Perhaps it may be going too far to say that those who habitually disregard cleanliness, and prefer to be dirty, have no moral perception; but it may be truly said that those who are morally sensitive are the more so from respecting this virtue. There is a close affinity between moral depravity and physical degradation. The vicious poor are always shockingly filthy: the depraved rich are visited by worse penalties: they may have clean garments; but what can wash away the impurities which vice has made part of themselves? It is not for one's self only that the virtue of cleanliness commends itself. Every one comes within the observation of others. However uncleanly one may be himself, he is not the less offended at the like neglect in those whom he observes. Now it is every one's duty to himself to recommend himself to others, so far as he innocently and reasonably can, and to obtain their respect. Clean and costly garments may fall very short of doing this if it be seen that they are a covering for the neglect of this important law. If there be a lovely object to the human eye, it is a clean, clear-faced, healthy, innocent, neatly-clad, happy child. There are few children who may not, if they will, be neatly dressed, for this does not depend on that of which the dress is made. There are fewer who may not have a clear skin, and healthy look, if they are properly fed, and sleep in pure air. There are none who may not have a clean skin; for we speak to those who are old enough to judge for themselves. And let it be added, for their inducement, that in obeying the command to be clean they are performing a moral duty; in neglecting it, they are inflicting an evil on themselves in two ways—first, in diminishing their own health and comfort; and secondly, in losing the esteem of others.

## AIR.

Among the generally unknown causes of loss of health, is the respiration of impure air. The congregation of many persons in one apartment, especially when artificial light in great quantity is permitted, is a cause of more maladies than is commonly supposed. Three causes, in such case, combine to destroy the fitness of the air for respiration—the animal heat of the assembly, the lights, and the breathing of the same air again and again. There must be such assemblies. The remedy is proper ventilation. The smoke of lamps has frequently occasioned death. No lamp is properly trimmed if it emit anything more than a pure bright flame. It is a common practice to keep sleeping apartments shut up. If there be several persons in a small room which has been shut up for several hours, it would be shocking to know how often they must breathe again and again the same air, and how unfit it is to be breathed after it has once visited the lungs. Add to this the impurity of the air, which is continually in contact with the furniture prepared and constantly used for sleeping, in an unaired apartment. It is not mere nicety, or fastidious delicacy, which requires that the pure air should be admitted where the human lungs are in action, but it is a law as old as the creation of man, and cannot be disregarded. A skilful observer might select among many, from the appearance of the countenance, those who have just left an apartment in which they have been respiring for hours a spoiled atmosphere. No doubt that this cause, long continued, so affects the whole mass of blood as to bring on many diseases. If pure air be peculiarly necessary to any class of persons, it is so to children. We believe a more useful suggestion could not be made on the subject of health to the whole community, than to invite them to respect this law of nature—that there cannot be perfect health where the air is impure, and that this applies especially to apartments appropriated to sleep. Visiting friends are often put into sleeping apartments which have not been opened for days and weeks; this is far enough from kind treatment, however innocently it may be done. (For further information, see No. 45.)

## TIME.

Every person connects himself, in his usual thoughts of himself, with all the lapse of time in which he can remember, and with all the lapse of time through which he expects to live. This he calls his life. He does not live in time that is past, nor in time that is to come. He actually lives only in the present moment. Yet he feels that he lives in the past, and will live in the time to come, because the past, the present, and the future are so connected that he cannot separate them. It is thus a law from which no one can free himself, that he shall suffer in the passing moment for the wrongs done in time gone by, and for the evils of which he dreads the approach. As this is certainly so, how little does he regard the operation of inflexible law, who provides for himself a load of self-reproach, for any gratification which he can procure by error or by crime!

Let us lay out of the case those errors and crimes which have been alluded to, and consider negligences and follies. Man was meant for action, and his actions were intended to enable him to secure good to himself. Good to himself depends on the performance of his duties to himself. Duty to himself requires that he should improve his faculties, and should avail himself of all the opportunities given to him for that purpose. The hours, then, which are permitted to slide by without any improvement, are lost. In so losing them, he breaks the law of the Creator. Apply this to the vocations in which one is to cultivate his mind in any business, mechanical, scientific, or learned. When one sees himself surpassed by others, and left far in the rear; when he is called on to measure himself against another; and when he sees that comparisons are made between him and others, greatly to his disadvantage—he may feel, and most men do feel, that they are thus depreciated because the precious time which was allotted to improvement has been passed in trifling amusements or in idle pursuits. To some minds, the suffering from such causes is extremely acute. They have no one to blame but themselves. The bitter remembrance which they have of the past, as connected with the present and the future, is the punishment for breaking a positive law. They may console themselves perhaps with the firm resolution that they will repair the wrong done in the past time by diligence in the time to come; but they find that time brings with it its own demands. They are fortunate, indeed, if they can do in one space that which belongs to it, and that also which belonged to another and in another season of life.

One cannot innocently say his time is his own, and that he may dispose of it as he pleases. His time is his life. It is given to him in trust. Like other trustees, he will be held to an account, in which there is no possibility of concealment, and where nothing will depend on proof. It may be supposed that it will be said to him, There was confided to your use a term of time; you knew, or could know, the laws prescribed to you in performing your trust: are you come from that trust to render an account of it, burthened with reproach from your own conscience, and with marks of guilt which you cannot hide! or, are you come without any advancement in the knowledge of your duties, and with no other account than that your days rolled by in childish pursuits or idle amusement, *no wiser* when you were severed from the world than when you left the cradle of infancy! or, are you come with the exalted acquisitions which you might have, and with that innocence and purity which you would have, if you had read the laws of the created world, and those which have been revealed and placed before your eyes! Where have you read in these laws, that no duties to yourself, and to your associates, nor to the *Lowly*, were enjoined upon you! Have you not been told by every breath you drew, by every movement of your frame, by every thought of your mind, by every just pleasure that you have had, by every pang that you have suffered, and by all that you have been made capable of perceiving and learning, that there were laws prescribed to you,

and that an account of your stewardship would be exacted from you by a Judge who cannot be deceived!

## SELF-LOVE.

It is an invariable law of nature that every human being shall do those acts which he thinks will secure good to him, and that he shall avoid those acts which will occasion evil to him. Why, then, should not every one do any and every act in his power by which his own will may be gratified, and avoid doing any and every act which is disagreeable to him? The only answer that can be given is, that man is a free agent, intrusted with the power, and charged with the duty, of ascertaining for himself what is good and what is evil; and that this power and duty extend to those with whom he dwells in society, and also to his Creator.

Children always conform to the natural impulse of self-love, until they learn from the discipline which is applied to them, that they cannot have their own will without subjecting themselves to a suffering, the dread of which controls the natural impulse. They learn, after a time, that the greater good lies in giving up what they will to do, and doing what is required of them, rather than to meet the certain consequences. We think that the whole science of morals will be found in the principles contained in the truth above stated.

Self-love is just as strong throughout life as it is in childhood. It is that quality of our nature to which all excellence may be referred; but it is also that to which all unworthiness may be referred. As the dread of punishment, or an unwillingness to displease those whose kindness a child desires, will restrain him, or put him into action; so, in more advanced life, the dread of suffering a certain or probable evil, and the certainty of losing the good-will of others, will restrain or impel to act. With those whose minds have been properly disciplined, and who have learned to comprehend their relation to the Creator, there is a far higher motive, which is founded in a submission to the Creator's laws. As one goes on in life, he may or may not acquire more and more clear and just perceptions of what will be the greatest good to himself, and how he can obtain it. It is a self-evident proposition that if a person could certainly know what it would be best for him to do, or not to do, in relation to all things and persons, and under all circumstances, and if he should conform to this knowledge, he would best obey the impulse of self-love, and most exactly conform to the laws prescribed for his permanent wellbeing.

It cannot be too often impressed upon the youthful mind that *life is to be taken as a whole*: for if this extended view be not taken, it must frequently happen that it will seem right in certain circumstances, and when the view is limited to these circumstances, that certain acts may be done or avoided as the greatest good. Yet, if the consequences could be foreseen, they would disclose that this seeming good would turn out to be a positive evil. It often seems good to the young to avoid the performance of labours which are assigned to them, and to spend in amusement the time which should be devoted to fit them for duties which will be incident to their future condition. This misapprehension of good is to be lamented; but with some this is not all. Their own self-love prompts them to engage in a course of folly, so that not only do they fail to obtain that which is real good, but they find, under the mask of pleasure, that which proves to them to be in the long-run the most grievous suffering.

The same truth runs, in an endless variety of forms, into manhood, and through all the stages of life. We are impelled by self-love not only to provide for the craving wants of our nature, but to seek pleasure, riches, power, distinction, and luxuries. These propensities are given for wise and beneficent purposes. It is the misapplication of them, as seen in the world, which constitutes human misery. He is called brave and honourable who defends himself, even at the risk of life, against those who would do to him that injustice and wrong which would make the gift of life of no

value. But the brave, who invade the rights of others, and subject them, by violence, to losses and to sufferings, without cause, misapply this principle of action. To get riches by honest industry, or the reasonable exercise of one's talents, is a commendable use of self-love. To get riches by unfair and dishonest means, to hoard them up, and to brood over them in secret, is a pitiful misuse of this commendable impulse. To have power over one's fellow-men, and to use it faithfully, and for their benefit, is a relation which one may honestly and commendably desire, as a reasonable exercise of self-love. To seek such power by deceitful representations, and to obtain it by violence and fraud, and to use it for purposes of supposed self-benefit, and to the injury and oppression of others, is another form of self-love. But there are few, if any cases, in the history of mankind, in which self-love has appeared in the latter form, without eventually overwhelming the agent with disappointment and sorrow. It is true that for a time such a one may seem to flourish in his schemes, and command the applauses of those who look up to him in his apparently fortunate elevation; but, in the very nature of things, if his heart could be sounded, there is no one whom he looks down upon who is not more at ease than himself. His day of humiliation may be at hand, in the course of events which he cannot control; and if not, he learns, when it is too late to correct his error, that he has misapplied the impulse of self-love. This misapplication is to be seen in many cases of daily occurrence, and in things of little, as well as in those of comparatively great, importance. The principle is everywhere the same.

We shall be answered perhaps that all this is incident to human nature. There is no help, it is said, for these evils. Every boy who has learned Latin repeats the maxim, *Humanum est errare* (It is human to err). A more mischievous maxim was never invented. If men understood, as most certainly they may do, that they need not err, and that it is best for them they should not, they would rather adopt as a maxim that none but the wilfully ignorant, and the wilfully foolish, err. Such a state of things is yet afar off. It may seem to be foolish, indeed, to assert that any society should ever come to be so well informed as to make a proper use of self-love. Let us not despair. We may improve very slowly; yet, if every one does even the little that he can, in showing, by precept and example, what things a rational and accountable being should desire, and what he should avoid and reject, certainly the time may come when self-love will never be so misapplied as to be necessarily followed by suffering, by penitence, and sorrow.

Will it be denied that there is a certain best course of action for every human being in every possible condition in which he may find himself? Or, that no small proportion of human suffering arises from not having discerned that it was best, in past circumstances, to have acted differently, or not to have acted at all? Or, that whether one did or did not act, in the supposed case, that his motive was to secure to himself the greatest good of which that case was supposed to allow? If these things cannot be denied, then the great end of life is so to regulate self-love as that it may secure the greatest good. Let us suppose that every person in society knew what it would be best for him to do or not to do, so that his physical, intellectual, and moral condition should be as good as he could make it. His self-love would never be directed to any end which would impair his bodily powers or keep his mind in ignorance, or misinformed, or make him a subject of reproach or contempt in his own view, or in that of others. This, it will be said, is an impossible state of things. So it was said that it would be impossible to root out the use of *ardent spirits*. This great change is not wholly accomplished; but does any one doubt that great advance has been made towards its entire abolition? Let us go on, then, in the work of improvement. Let every one try to show the proper uses of self-love. The day may come when every one will admit that all the sufferings

which may visit the human family are of their own making, those only excepted which arise from the general laws of the Creator. Even as to those, they may be greatly mitigated by intelligent moral agency; and when they do come, they can and will be endured with piety and resignation, if the sufferer can console himself with the certainty that he has done no wrong thing, nor neglected any proper one, to which the cause of his sufferings may be referred.

#### LABOUR.

It is commonly considered that labour is the *curse* declared to mankind, as a consequence of the transgression of the *first man*. It is foreign to our purpose to enter into any discussion as to the true meaning of this historical or allegorical account; the Christian revelation may not be dependent on a literal understanding of it. However this may be regarded under the influence of further reasonable research, we must take man as he is; and so considering him, labour is not an *evil*, but a *pleasure*. Is it a curse to man, as he now is, to be enabled by labour to comprehend the existence of the Deity, and the beauty and utility of His works? to adorn the earth, and bring its productive powers into action? to apply the material substances of the earth to reasonable use, convenience, and ornament? to expand and improve the human mind? to cultivate and strengthen the moral power? to secure and enjoy the comforts of a well-regulated society? Certainly these are the effects of labour; and labour so applied constitutes man's highest object and happiness.

There are two kinds of labour:—1. Mere bodily labour; 2. Labour of the mind. These two are sometimes necessarily combined. The mind and the body demand some sort of employment. No one whose mind is free from natural defect can prevent its action. It will think of something, good or evil, profitable or foolish. Every one who attends to the operations of his own mind, must be convinced that this is so. The body and limbs cannot be kept in any one position for any considerable space of time, unless they have been in action and demand repose. If it were painful to us to direct the action of the mind to useful labour, and if it were distressing or inconvenient to us to exercise our muscles for purposes which we believe to be proper, then it might be that labour is a curse; but many, nay all, who require of the mind to perform its duties to any useful purpose, and especially those who have disciplined the mind to an accustomed service, find that the absence of employment is an affliction. We cannot see how this should be otherwise, if we rightly comprehend man's relation to the mechanism of the universe, of which he constitutes an essential portion.

As to bodily action, it is seen that children in their sports go through a series of exertions, often exceedingly violent too, from mere pleasure. Men frequently exercise the body much more severely in matters of amusement than they have any occasion to do in necessary labour. This action seems to be a dictate of nature. In many cases of indisposition, bodily motion is the prescribed remedy, and is commonly a successful one. There are sound reasons why this should be so. There is a universal action of the material system to which man belongs, and a continual waste and demand for supply. Excepting only in the involuntary movements in man's structure, which are not confided to his care, he is required to aid nature in her operations. If he would put himself in the best condition to receive and derive pleasure from his daily food, he must keep himself in action. Those who have the least pleasure in using what was given to be used as the means of pleasure to the senses, are those who keep the body inactive. This is true of those who labour with the mind only; more strikingly true of those whom affluence excuses from labour of body and mind. They seek happiness in indolence and in luxury: they find it not, because they violate a law of nature. No product of the vineyard, the field, or the sea, however aided by inventive art, will furnish a welcome repast to one who sits in list-

## THE PRIVATE DUTIES OF LIFE.

less idleness, on a downy cushion, from breakfast-time till dinner. The day-labourer who sits down to his coarse meal, has a pleasure to which the luxurious idler is a stranger. The one receives a rational benefit from the kind and just bounty of nature; the other seeks it where nature has decreed that it shall not be found.

The labour of muscular action is not only in itself a pleasure, but it is the means prescribed to us for the acquirement of subsistence; for the gradual improvement of society; for applying natural and artificial products to our comforts, to our convenience, and to reasonable luxuries. Nor only so: this is the groundwork of all the beautiful and imitative arts; of the discovery and application of the chemical power of matter; of the wonderful contrivances by which man securely moves on the face of the ocean; by which he cultivates his acquaintance with the stars, and raises his thoughts to the Author of all being. Let us not, then, regard labour as a curse, but a blessing, and rank it among the many causes for thankfulness. It is obvious that muscular action would have been given to us in vain, if it were not directed by intelligence. There must, then, be labour of the mind. This is nowhere said to be a curse. If there be anything for which we should be specially thankful, certainly it is that we are blessed with the power of mental exertion. This labour is in itself an inexhaustible source of happiness; and in its fruits has made, out of savage man, a rational and improving social being. The most restless and comfortless of all creatures is he who has no occupation for his mind. If one would invent the most miserable condition for a human being, other than mere physical suffering of the most excruciating kind that can be without extinguishing life, it would be to deprive him of all employment of body and of mind.

Can there be a doubt that, in man's present condition, the ability to labour is his exalted privilege? And is he not accountable for this privilege? Is not reason given to direct him in the use of it? It is well known to those who have compared the condition of mankind in different ages, how much the labour of body and mind have been able to accomplish. Even within the last half century, the most surprising changes for the better have taken place, from the right use of this productive power. On this depends the civilized condition of the human family. From the joint labours of all who wish well to their fellow-men, there will be obtained, eventually, the knowledge of the best manner of using the products of the earth, the best mode of instructing and directing men in their social relations, the just homage due to the Creator, and the true purpose for which human life has been given.

To some descriptions of persons labour is irksome. They are obliged, in their vocations, to use certain muscles, and those only. They repeat the same act throughout the day. Their labour becomes tedious, because it requires little or no action of the mind. To this numerous class we venture to offer a relief which is within the easy reach of many of them. It is well known that the nature of habit is such, that the hands will do what they have been accustomed to do, without any obvious attention, and the mind is left to do what it will. The mind might be employed while the hands are busy, in pursuing some connected train of thought. Muscular action, so far from being an interruption to the action of the mind, may be made to assist it. Persons who think intently are often seen to have some habitual movement; and we have heard several persons acknowledge that their best ideas had come to them when they were engaged in some simple occasional duty, such as the folding of paper, or the cutting of the leaves of a book. The stir of body seems to produce a corresponding stir of mind. The relief which we suggest is, that sedentary labourers should provide themselves with subjects for reflection, and exact of their minds to attend to these subjects. By such simple means the memory may be strengthened, the stock of knowledge may be greatly increased, and the mind surprisingly invigorated. One might begin this exercise by attempt-

ing to remember, with the utmost precision, every act done during the preceding day, and so go back from day to day. Better still would it be, if the purpose were to see wherein one had not done as well as he might, and as he may wish he had done. This exercise may be applied also to the contemplation of subjects suggested by reading; and this contemplation will raise questions which will lead to the examination of books. There may be hundreds of poets, philosophers, and moralists at the work-benches in this country who have no thought of themselves that they are such. It is in the power of any person who can read and understand the English language, to strengthen his memory, give himself an interesting employment, and furnish himself with a rich fund of the truest philosophy, in this manner. He may commit to memory six lines each successive day of Pope's 'Essay on Man,' and on each day repeat all he had learned on preceding days. On the 218th day he would be able to repeat the whole essay. This might be done without losing one moment of time, and without making the slightest error in one's work. When accomplished, it would be an intellectual treasure for which any man might be thankful, and of which he might be justly proud. The first efforts may be discouraging, but perseverance will ultimately insure success. Every one who is accustomed to thinking can attest that most new subjects are at first confused and undefined; but that they gradually disclose themselves, and fall into shape and order, just as material substances used on the work-bench and the anvil take that form, smoothness, and polish, by successive operations, which the workman requires.

### HABIT.

This quality of our nature has engaged the attention of many philosophic minds. It has been considered an *ultimate fact*, as it is called; that is, one of those qualities which, like respiration, digestion, and many others, are found to exist; and beyond which fact no investigation can be made. Its laws, rather than its nature, have been the subject of remark. It may be that habit is to be referred to the law of action, which appears to pervade all material and intellectual being. Life is divided into parts: in one we are awake, and active; in the other, wrapped in sleep, and quiet. Each successive day is a sort of new existence, in which we are to repeat many of the acts of the preceding day. We repeat these acts because nature demands the repetition of them. Also, almost every one is engaged in some vocation, on which he relies to supply his wants and gratify his wishes; and most persons have in view certain pleasures, which are innocent or otherwise. It appears to us that habit arises from this demand for action, and from the manner in which this demand is supplied. Action relates to ourselves, to other persons, and to things around us which minister to our wants; supplying its demands associates us with these persons and things. The want, whatever it may be, arises, and forthwith all things connected with satisfying it force themselves into notice, and these become a part of our very existence. It is a well-known fact, for example, that the appetite for food will associate itself with a particular hour of the day, and with persons, places, and objects of gratification; so that one becomes hungry rather according to the hour than the natural want.

It may perhaps be an ultimate fact, beyond which we cannot go, that those acts are most easily and well done which are oftenest done. One who uses a flail, an axe, a scythe, a sword, or a pen, can use either the better the oftener it is used, until he arrives at a point of excellence at which his power of improvement stops. This may perhaps be accounted for by supposing that the first effort which the mind makes to direct muscular action is the most difficult one. After repeated efforts, the mind seems to understand better and better how to direct, and the muscles how to obey, till at length a very slight effort of the mind seems to be all that is required, and even an effort so inconsiderable and rapid as not to be the subject of notice. On this truth seems to depend

the astonishing facility of action to which (among many other instances) jugglers and musicians attain. This is called *habit*, which word is derived from a Latin word which signifies custom or use. There are customs or habits of the mind as well as of the muscles. Persons who accustom themselves to extemporaneous speaking, acquire a surprising ease and readiness in the complicated action of conceiving, uttering, and expressing, by sounds, by looks, and gestures, whatsoever they would impress upon an audience. The mind has its own habits also, in the quiet of contemplation, and in exercising its various powers. It has its own associations, too, with external objects, of which many curious instances are stated in philosophical works.

The moral deduction which we make from these general principles is this—that there is a continual craving to do some act, to obtain some object; or a continually-recurring necessity to do some act, to prevent an evil or inconvenience. The frequency of this call upon us to do something, whether it be for eventual good or evil, leads to the practice, custom, or habit of doing; and in some cases the impulse to act becomes so powerful, that reason, self-respect, the laws of society, and even those of the Lawgiver of the universe (if these are heeded), present no sufficient barrier to the impulse. It is to this all-important truth in the nature of man that we earnestly invite the attention of the young. The capacity to create habits is the consequence of the power given to us to promote our own welfare, individually, socially, and as accountable beings. This capacity was designed to fasten us down to that course of action which will accomplish these ends of our existence. Like everything else with which we are intrusted, it may be rightly and profitably used, or may be misused, and perverted to our certain ruin. Habit is the kindest friend or the cruellest foe to human welfare. When it assumes the latter character, it approaches us in the most deceitful and seductive forms. It comes wearing attractive smiles—it delights—it fascinates—it substitutes its own irresistible will for our own—it triumphantly points to the gulf to which it onward bears us. The fly caught in the spider's web is a faint illustration of the power of habit. He knows from the first moment his destiny. The gambler, the drunkard, and the felon, when and how do they learn that they have been caught in the web of habit!

#### INTEMPERANCE.

This word has attained a meaning more limited than its proper one. It is applied commonly to persons who take habitually ardent spirits; but it is equally applicable to all transgressions of the law of moderation. All acts which may be lawfully done for one's own good, when carried to excess, are acts of intemperance; and all such acts are sooner or later followed by some sort of suffering, according to their nature and degree. Excessive labour of body or mind is as much an act of intemperance as to make one's self dull and stupid by taking food, or irrational and giddy by taking spirits. But there is a wide difference in the degree of immorality in the kinds of excess. An intemperance in study, which brings untimely death in some instances, is not condemned as an immoral transgression (though it certainly is such), for the motive which leads to this intemperance is regarded as an honourable one. The loss of health and character, from abusing the privilege of taking nourishment, is universally condemned, because the motive, and the acts done in obedience to its impulse, are irrational and disgraceful.

There are two kinds of intemperance against which the young should be warned: the one is drinking, not for nourishment, but for pleasure; the other is, using tobacco. It has been already demonstrated that nature requires a certain quantity of proper food to maintain a healthy and happy condition of body and mind; also, that excess of any kind will be followed by suffering. This is just as certain as that a full vessel must throw off just as much as is added to its contents. It is very natural that young persons should assemble for the

sake of society; being assembled, they must have some employment for the muscles of the body and the craving of the mind. We have shown that such propensities spring from natural constitution, and that they must be satisfied. There must be a community of purpose in the meeting. That may be found in any muscular action in which all can join, and which has some definite object, as athletic games; or it may be found in some intellectual employment which is common to all present. Unhappily, the most frequent bond in such meetings is to *drink*, for in this all can join. Connected by this common attraction, the mind is called into action; but for what purposes! Those who frequent places of public entertainment can best answer this question. Some who are sent to public seminaries can also answer it; and some can answer it who know that they are maintained *there* by pinching economy *at home*. Some others could answer it, who never had a serious thought why such places were established, nor for what uses they were intended.

We refer again to the demonstration heretofore made, that the law of nature, which cannot be broken with impunity, inexorably admits so much, and no more. Let us, then, look in upon a gay company of young persons around a table, and half concealed by tobacco smoke. What sort of air are they breathing! what sort of substances are they casting into their physical system, already bursting with excess! what sort of thoughts have they in their minds! and what sort of words are usually flowing from their lips! We *could*, but will not, answer these questions for them. Let us pass by this revel, and go to the next morning. We might then propound some other questions. Are not their heads heavy, hot, and throbbing! Are not their eyes thick and burning! Are not their tongues white and parched! Do not the nerves tremble! Is not the mind muddy and confused! In what condition are they to perform duties to themselves, to those they serve, to instructors, to affectionate parents! *Is not this dear-bought pleasure!* How long can nature bear to be *pleased* in this manner! But the matter does not stop here. The same scene is repeated again and again. *Soon habit asserts its awful dominion;* and then the scene *must* be repeated. The craving is insatiable, and cannot be resisted. From social drinking, the step is an easy one to solitary drinking. *There is no resting-place for habit; everything in this system of being must keep on, or be at an end.*

It is believed that the sort of criminal excesses to which we allude are not from the promptings of nature. We venture to assert that they are entirely artificial in the beginning. It seems irrational that any one should like to take more of anything than nature requires; and more so, that one should naturally desire to take burning liquors to the degree of intoxication, or perhaps to take them at all. It is believed there is no such natural propensity; but that such liquors, when first taken, afford less pleasure than pure water. The taste for these articles is created by association, by imitation, by fellowship; and, above all, because there is a kind of tradition that it is *manly* and *social* to drink. Songs in praise of the juice of the grape, and of meaner liquors, have some effect in the delusion of drinking. There is a fascination in combined poetry and melody. Such combinations are well known to have the most powerful influence in national associations. They inspire a feeling which bears men on to victory or to death. The songs of Bacchus do the same. They conquer the strength of those who sing, and of those who listen to them, and sometimes lay their admirers not in a bed of honour, but of contempt.

If one could get the ear of such a misguided youth, he would not do much by reasoning with him. He might do something by getting him to reason for himself. It would be necessary to bring to his view some facts from which he could reason. He must be made to know what a wonderful contrivance the digestive power is, and by *whom* it was contrived. That its purpose is to take the inanimate substances which

## THE PRIVATE DUTIES OF LIFE.

nature provides for it, and convert them into living sensitive being, and possibly into thinking power and immortal spirit. He must be reminded how easily every human contrivance may be deranged, and the more so, and irreparably, in proportion to the minuteness and delicacy of construction. But as one might fail to make a thoughtless boy comprehend the nature of the principle of life which resides in his own bosom, because he cannot see it, some illustration must be made. Unhappily there is none which can be effective to this end. The nearest which occurs to us is this. Let us suppose, then, one knows the use and the value of the human eye in its physical, intellectual, and moral relations; that he knows he must take care of it, and frequently bathe it in cold water, as well to cleanse it as to refresh and brace it, so that it may still be an eye to him, when decline and old age shall come. Let us further suppose that, instead of so using and so preserving this delicate organ, he should, when he first rises in the morning, let fall into it a drop of burning spirit, and at eleven o'clock another, and so on, at the proper hours, until he sleeps again—how long would the power of vision remain to him, and how soon will this organ of delight become a source of insufferable pain? It must be much the same with the digestive organs as to the abuse of them.

If one could in some such way bring home to the perception of an erring youth the grievous wrong which he is inflicting on himself, he might be prepared to reason on his own case, and might be asked some such questions as these:—Is it of any consequence to you to be free from suffering and sorrow? As you must inevitably keep company with yourself as long as you live, is it of consequence to you to make of yourself a pleasant and agreeable companion, and not one who will be continually complaining and upbraiding? Is health of any value to you? Can you use your limbs, and the faculties of your mind, as you would like to do, without it? Can you have health, if your habit is to throw into that delicate part of your system whereon the action of life depends, substances which excite it to an unnatural exertion, or deprive it of all power of exertion? Does not every part of your system sympathize with the injustice which you do to your digestive organs? Will not your brain, and consequently your mind, suffer by this violence? Do you expect to attain middle age and old age? Will not the seeds you are now sowing come up in that space of time? Will they come up in the form of enfeebled muscles, chronic aches, self-reproaching thoughts, the loss of the capacity to enjoy the bounties and beauties of creation? Will they grow up to overshadow your moral sense, and shut out the delights of intellectual power? Was life given to you for the few years in which you can sing, drink, and 'enjoy yourself,' or that you may enjoy life in every stage of it, as a rational being, and by rendering your homage to nature in obeying her laws, and your gratitude to Him who ordained these laws for your happiness? Do you not look forward yourself to be at some time a parent? Have your own parents ever so conducted themselves towards you that you have a right to punish and afflict them? Are you willing that your parents should see you and know you as you know yourself? If you should be a parent, are you willing that your children should be told with whom, and in what manner, you 'enjoy yourself?' Would you tell them how you spent your youthful days and nights, and recommend to them to take yourself as an example?

### TRUTH AND FALSEHOOD.

These two subjects relate to two parties:—*first*, The individual who speaks truth or falsehood; *secondly*, The individual to whom it is spoken. We propose to consider this matter only in relation to the former party, and as to him in two views:—1. Whether there be any, and what law, which requires that the truth should be spoken; and, 2. What good or evil one may do to himself by lying.

1. One reason why truth should be spoken is, that

the knowledge which any one person can have from the use of his own senses, in many things which it most materially concerns him to know, is very limited. He must therefore often depend for his knowledge on what others say to him; and when the thing spoken of is exclusively known to the party speaking, the other must rely entirely on what he says. If, therefore, it be considered how great a part of the most serious concerns in life proceed on declarations made by one person to another, we may readily conceive, that if these could not be relied on, the affairs of mankind would be greatly embarrassed, and confidence in each other would be destroyed. As this matter of speaking the truth is one which concerns all persons, so all persons agree in holding liars in contempt. Even the very lowest persons consider themselves to be disgraced when charged with the guilt of lying. They can endure charges which would subject them to public punishment, with more composure than they can endure this. A lie is always understood to be resorted to to secure some advantage or prevent some evil to the person who resorts to it; or to occasion some disadvantage or injury to the person to whom, or of whom, the lie is told; sometimes both these purposes concur. The object in view is always an immoral one, and the means used are always regarded as disgraceful. It is at once obvious that wilful falsehood is forbidden by natural law, which is intended to regulate our social relations, and is expressly forbidden by Divine law, which condemns all acts of fraud and deceit, and commands us to do to others as we would have them to do to us.

2. It is a rare occurrence that any one who descends to falsehood succeeds in the object which he may have in view. He is commonly detected, and if not, is suspected, which may operate quite as much to his disadvantage. If he should escape detection and suspicion, he lives in constant fear of both. He has a very troublesome secret to keep. If he should be able to do this, still he cannot hide it from himself that he is a liar; and such a person, by natural justice, is compelled to pass that sentence upon himself which he knows that others would pass upon him if they were as well informed as he is. A liar is therefore obliged to feel like a guilty person, and a habitual liar very soon comes to look like one. If there be no higher motive than one's own interest and welfare in speaking the truth and avoiding falsehood, this is a very sufficient one. If a man is known to be a person unworthy of confidence when he speaks, he has not the benefit of being credited even when he speaks the truth; he voluntarily deprives himself of the advantages of social life; his assertions secure to him no credit; his promises are contemned; he makes himself to be alone in the very bosom of society, for every one shuns him. In the administration of justice in courts, a person is not regarded as a witness whose common reputation is that he is not believed when he speaks. The objection to him is not that he might not tell the truth in the matter which is on trial, but that such a person ought not to be received as a witness because he cannot be credited in anything that he says. When such a person has been called and examined as a witness, it is usual to examine other witnesses to prove his character; and if it be proved that he is unworthy of credit, what he has sworn to is disregarded, though he may have declared the truth. This is the common fate of all such unfortunate persons in society as well as in courts. Independently of the criminality, lying is very poor policy. If the object be to obtain a supposed good, it rarely is obtained by such means; and if it be, the price so paid must always be greater than the good is worth. If the object be to conceal a wrong done, it is rarely successful; and if not, it leaves the offender without excuse for his error, and adds another wrong. If the object be to charge an innocent person with a wrongful act, or to deprive one of his good name, or of some lawful possession, or subject him to some evil which he ought not to endure, the offence is of that cast which the law of the land holds to be *malicious*, and it deals with such offences

accordingly. In short, it is very difficult to violate any law of natural justice or Divine prohibition without encountering an adequate punishment; and it may be assumed that the punishment which follows lying is as certain and just as in any instance of criminality. If every tenant of every prison, and if every person who is in the custody of a goading conscience, were asked this question, *What was your first step from innocence and purity?* he would probably answer, *Telling a lie!*

## SINCERITY AND INSINCERITY.

These are other names for truth and falsehood. They are not commonly applied to the most serious concerns of human life, but to what are called the 'imperfect obligations.' Such obligations, it is well known, are not enforced by the law of the land, but are binding as duties arising as well from natural law (reasonably expounded) as from Divine law. Sincerity is a duty to one's self, because it is demanded by self-respect. As every one has an individual separate physical being, so every one has a *separate circle* within which he exists, and into which no one has a right to intrude. His thoughts, motives, opinions, and policy are his own. What he will or will not do (so that no wrong be done to others, and no act of duty be withheld from them) is for him to decide upon. Within this circle he makes up his judgments on all persons and things. In his outward deportment he must frequently act in a manner not consistent with these judgments. As an example: one has made up, from repeated observations of a certain individual, a very clear, but very unfavourable judgment of his qualities; but there is no occasion to disclose what the judgment is. The observer is obliged, or finds it convenient, to meet this individual, and to deal with him, and perhaps to interchange courtesies with him. It is undoubtedly proper to manifest the respect, in such a case, which the decencies of life require, and to show the common proofs of goodwill. There is no insincerity in this. Though no one can possibly avoid forming judgments of others, nor avoid liking or disliking them, even including very near friends and relatives, yet there may be a positive violation of duty in publishing these judgments or in disclosing these feelings. The Divine law, 'Judge not, that ye be not judged,' does not, it is believed, interdict these judgments, because they cannot but be made; but it forbids the wanton, unnecessary, and injurious publication or manifestation of them. Those who are keen observers of their fellow-men, see in their faces, in their manners, in their modes of speaking, in their tones of voice, in the sentiments which they express, &c. causes for respect, esteem, confidence, and approbation; or they may see causes for disrespect, suspicion, strong disapprobation, and disgust. But all these things belong to the *individual circle*. It is not insincere to keep them there. On the contrary, society would be intolerable if they were not kept there; it is very hazardous to the observer to let them out unnecessarily. He may be mistaken both as to the favourable and unfavourable judgments which he forms. Further observation, new circumstances, unexpected changes, may essentially correct his judgment, and therefore a prudent man will keep them to himself: they are his own peculiar property, and were obtained for his own use. The worst form of insincerity is undoubtedly that which leads one to pretend to feel a warm friendly interest in the welfare of a person who is an object of indifference to him. This is a charge which has been frequently brought against the dispensers of patronage. There can be no doubt that public men, from their peculiar situation, are liable to be greatly annoyed by applications for the exercise of their influence in behalf of individuals in whom they take little or no interest; and in replying to these applications great caution and delicacy require to be employed, lest, on the one hand, they give offence by their bluntness and sincerity; or, on the other, excite expectations which they have neither the ability nor the intention to fulfil. The petitioners may be over-sanguine, and may, from

the courtesy of the reception they meet with, be led to entertain unreasonable hopes which are destined to be disappointed; and therefore it is incumbent upon those to whom the applications are addressed, while they say nothing that can offend the delicacy, or hurt the feelings of the applicants, to express themselves in such a manner as not to excite any hopes which they are not only able, but willing to realise. The same rule ought to be observed by individuals in every station of life; and then fewer disappointments would take place, and more confidence would be entertained between man and man in the unavoidable intercourse of society. Insincerity is often demonstrated by paying false and silly compliments, which assume the form of *flattery*—a word which is derived from the Latin, and signifies wind, breath, puff. This is a kind of aliment which perverted self-love finds to be exceedingly pleasant. Although it is in truth precisely what its origin indicates, there is hardly a man, woman, or child who is not disposed to partake of it, if it be artfully disguised. But, on the other hand, all sensible persons, of whatever age or sex, who see what it is, and why offered, feel for the flatterer the contempt which he deserves. This insincerity is, and ought to be, deemed a high offence. It implies art and deceit in the flatterer, and sufficient weakness in the flattered, to be subdued to the purpose in view. The flatterer's purpose may be to secure to himself no more than a better esteem than he can have any pretence to, and it may be, through that, to secure to himself something which may be very costly to his victim. All extravagant commendation of any person, however estimable may be his qualities, and however highly they may be appreciated by the bestower of the praise, ought to be avoided. The praise may be perfectly sincere, but still it is a violation of good manners, and is a direct insult to the understanding of the person to whom it is administered. Sincerity requires no such breach of the other moralities; and whenever it is exercised in such a manner, it degenerates into *rudeness*.

## CIVILITY.

The well-being of society would be greatly promoted if the nature and use of this Christian virtue were more generally known. We take this to be, in personal intercourse, the observance of the command, *Do to others as you would that others should do to you*. The most rapid glance at any community shows this—that some of its members are brought into contact, in matters of business, necessarily; others meet, incidentally, who have no particular connection; others meet for social purposes, in various forms; and that there is a large proportion who know of each other very little beyond the fact, that they are of the same country, and perhaps not even that. There must be a *best rule* of deportment for all these classes; and no one will deny that if this rule were defined, and faithfully applied, there would be much more of everyday comfort and complacency in the world than there is well known to be. If we rightly understand the meaning of civility, it is the manifestation of kind feelings, and of a desire to do all things which are to be done under the influence of such feelings, in a becoming and agreeable manner.

If every person understood the true foundation of society, the common origin of all its members, their natural and necessary sympathies, their community of interests, their necessary action upon and with each other, it might be supposed that all who are reasonable would be civil. They would be so because they would promote their own good, because they would be doing what it is proper to do to promote the good of others; and because they would know that in so doing they would conform to the design of their creation. We do not include under the term *civility* the great duties of justice, acts of munificence, important personal services. These arise out of some special relation which an individual bears to one or more other individuals. It seems to be limited to the manner in which the common or accidental intercourse of the members of society in general should be carried on. This matter may be

better understood by some examples. Thus if one comes into the presence of another as a beggar, servant, labourer, mechanic, trader, merchant, farmer, lawyer, physician, clergyman, or public officer, or if it be a female, or child of either sex, there may be very various modes of receiving these different persons—yet certainly, by every one of the laws which we are endeavouring to illustrate, these several persons are entitled to civility. Even the beggar—perhaps one should rather say the beggar in particular—if not deformed by voluntary transgression, should be received with civility; that is, gentleness, kindness, decorum are to be observed relatively to each one. Why? Because no man can afford to be deemed insensible to the cause of reasonable humanity; nor a stranger to the decencies of life; nor ignorant of what is due from him, nor to him, in any of his proper relations.

There is perhaps no kind of incivility more contemptible than that which is exercised towards those servants of the public, who would be liable to the loss of their situations were they to resent—as they must naturally feel inclined to do—the insolence to which they are frequently subjected. It is no uncommon thing to hear young men giving their orders in the most authoritative and offensive manner to waiters at inns, stewards of steam-vessels, or any other class of functionaries whose services for the time may be at their command; and abusing the poor fellows who are doing their utmost to serve them for their stupidity and awkwardness, while they may all the while be performing their work in the most efficient and unexceptionable manner. And this impertinence they employ for the purpose of impressing those who may be witnesses of their behaviour with a favourable opinion of their smartness and knowledge of the world. They could not adopt a surer plan to defeat the object which they have in view; for every well-bred person will regard their conduct with disgust, and will look upon it as a sure indication of ignorance, impertinence, and want of sense. This is an error, however, which, in the great majority of instances, time and experience will correct. But we sometimes find similar conduct manifested by those who cannot plead youth and inexperience in justification of their coarseness and incivility. Such persons we are in general quite safe in setting down as individuals who wish to appear above the sphere in which they are entitled to move, and who, feeling that they have no claim to the character which they have assumed, endeavour to conceal their deficiencies from the observation of others by behaving in a rude and brutal manner to those who are prevented by their position from resenting such conduct.

There is one other consideration which operates on all men who have had much experience in the world. Men and things change, and take new and unexpected relations. Persons who have been long, and even intimately connected, suddenly or gradually sever; persons who have known little of each other, and that little uninteresting or unfavourable, are brought in contact by some unexpected turn of affairs. Sometimes one needs favours, or at least good-will, from those he never thought to be of the least importance to him. In such, and in a multitude of other circumstances, one may find the advantages of having been acquainted with the virtue of civility, which implies that one has given no unnecessary offence. There are other cases in which a person may be called on by duty to do things disagreeable to himself, and exceedingly so to others. But there cannot be any good sense in performing such duty morosely, and with inhumanity.

POLITENESS—GOOD MANNERS.

A refined species of civility is sometimes expressed by the term *politeness*, which is an exterior indication of good-breeding or good manners, and may be defined as that mode of behaviour which not only gives no offence, but which affords agreeable sensations to our fellow-creatures. In our intercourse with the world, this species of civility is imperative. We possess no

right to give offence by language or actions to others; and we are bound to conduct ourselves agreeable to the reasonable and set rules of society. Some severe writers on morals have confounded *politeness* with *insincerity*. They seem to imagine that the act of speaking gracefully to another is necessarily mere grimace, or an empty flourish signifying nothing. In many instances, with insincere people, this may be the case, but it is not so with those of well-regulated minds. It is always better to speak politely—that is, with extreme propriety and delicacy—than coarsely, sulkily, or impertinently. We say cultivate politeness of manner by all means, for it is *refined civility*, and will spare both ourselves and others much unnecessary pain.

Civilised society has in the course of time instituted certain rules in the code of politeness, which, though of little actual value, it is every one's duty to learn, because by knowing and acting upon them, we can make life glide on much more smoothly and pleasantly than if we remained in ignorance of them. These rules are sometimes called the rules of *etiquette*. We shall here briefly allude to a few of the more important of these social regulations:—

1. *Honour to the Female Sex.*—Women are physically weaker than men. They are unable to defend themselves from insult or injury, and it would be considered indelicate for them to do so, even if they possessed the power. For these and other reasons, it is only simple politeness and a sign of good sense to render any little service to women—to assist them when they appear in any difficulty, to speak respectfully of them and to them, and to give them honour whenever it can be reasonably required. It will be observed, therefore, in what is called good society, that women are treated with exceeding delicacy and deference: they are offered the best seat, or the only seat if there be no other; allowed to walk next the wall, or at the farthest point from danger, in the street; never rudely jostled against in a crowded thoroughfare; and are always parted from with a respectful bow. All this is considered essential in good manners, and attention to it will not in the smallest degree degrade any man in the opinion of the world. At the same time, as respects the women who receive these attentions, it is expected that they will not 'give themselves foolish airs,' or presume on the forbearance and kindness of the stronger sex. In fact, no female will do so who is acquainted with good manners, or wishes to avoid being despised.

2. *General Courtesy and Respect.*—It is incumbent on every one to be courteous or respectful in his intercourse with neighbours, acquaintances, or with the public generally. To inferiors, speak kindly and considerately, so as to relieve them from any feeling of being beneath you in circumstances; to equals be plain and unaffected in manner; and to superiors, show becoming respect, without, however, descending to subserviency or meanness. In short, act a manly, courteous, and inoffensive part in all the situations in life in which you may be placed. Society, for good and sufficient reasons, which it is needless here to explain, has ordained certain modes of address, and certain exterior signs of respectfulness, which it behoves us to support and personally attend to. In Eastern countries, as of old, it is the custom to uncover the feet and to sit down, in token of respect, on going into the presence of kings, or on entering any religious edifice or private dwelling. In our country, the custom is entirely the reverse. It is an established mark of respect to uncover the head and to stand, in the situations which we have mentioned, and to this point of etiquette we are bound to adhere. We must not, from any crotchet of our own, violate the rules or customs which society sanctions and enjoins, as long as these rules and customs are not opposed to reason and sound morals, and only refer to such trivial arrangements as taking off our hat, making a bow, shaking hands, or other matters equally unworthy of deliberate consideration. None but persons of a silly, eccentric turn of mind think of disputing about these trifles. On the same principle

we should give every one the title which, by law or courtesy, he usually receives.

3. *Personal Behaviour*.—A well-bred man is always known by the perfect ease and tranquillity of his manner. These are points to be carefully cultivated. Acquire, if possible, an easy confidence in speaking, so as never to appear abashed or confused, taking care, however, not to fall into the opposite error of forwardness or presumption. Persons moving in the highest circles of society seldom or ever allow themselves to appear disturbed or vexed whatever occurs to annoy them. Perhaps there may be an affectation of indifference in this; still their conduct is worth admiring, for everything like fidgetiness or boisterousness of manner is disagreeable to all who witness it.

Carefully avoid the following things in personal behaviour:—Loose and harsh speaking; making noises in eating or drinking; leaning awkwardly when sitting; rattling with knives and forks at table; starting up suddenly, and going unceremoniously out of the room; tossing anything from you with affected contempt or indifference; taking anything without thanking the giver; standing in the way when there is scarcely room to pass; going before any one who is looking at a picture or any other object; pushing against any one without begging pardon for the unintentional rudeness; taking possession of a seat in a coach, theatre, or place of public meeting, which you are informed belongs to another; intruding your opinions where they are not wanted, or where they would give offence; leaving acquaintances in the street, or a private company, without bidding them good-by, or at least making a bow to express a kindly farewell; slapping any one familiarly on the shoulder or arm; interrupting any one who is conversing with you; telling long and tiresome stories; whispering in company; making remarks on the dress of those about you, or upon things in the room; flatly contradicting any one, instead of saying, 'I rather think it is otherwise,' 'I am afraid you are mistaken,' &c.; using slang expressions, or words of a foreign language; acquiring a habit of saying 'says she,' 'says he,' 'you know,' 'you understand,' &c.; helping yourself at meals without first asking if you may not assist others to something which they would like; picking your teeth with your fork, or with your finger; scratching or touching your head; paring or cleaning your nails before company; mentioning the price of any article of food or drink which you are offering to guests; asking questions or alluding to subjects which may give pain to those you address; neglecting to answer letters. It would be easy to enumerate many other things which should be avoided as savouring of bad manners, but these will be sufficient to indicate the principle of politeness, and if that be understood, there can be no difficulty in knowing how to act with delicacy and discretion in all the concerns of life.

4. *Gentility and Vulgarity*.—By attention to the rules of good-breeding, such as we have just alluded to, the poorest man will be entitled to the character of a *gentleman*, and by inattention to them the most wealthy individual will be essentially *vulgar*. Vulgarity signifies coarseness or indelicacy of manner, and is not necessarily associated with poverty or lowliness of condition. Thus an operative artisan may be a gentleman, and worthy of our particular esteem; while an opulent merchant may be only a vulgar clown, with whom it is impossible to be on terms of friendly intercourse. Vulgarity of manner is often exhibited in its most offensive form by persons originally of humble birth and breeding, who have risen to wealth by the force of fortuitous circumstances. It is not uncommon to hear persons of this class, particularly 'ladies,' speaking of 'my coach,' 'my house,' 'my governess,' 'my family,' 'my servants,' 'my furniture,' and so forth; all which is *real vulgarity*, and indicates a low tone of breeding, and weak understanding on the part of the speaker. A man or woman of refined taste never alludes to matters of dress, domestic convenience, or things strictly personal, and rather endeavours to di-

rect conversation into those channels in which all present may harmoniously join.

#### ANGER.

One of the most important of our private duties is the due regulation of the passions. We naturally possess certain mental affections called *propensities*, which, when properly restrained, serve a good purpose, both individually and socially, but when let loose, or badly regulated by the understanding, lead to the commission of many vicious and abominable actions, which in moments of calm reflection, and when our conscience is aroused, we deeply lament and regret. Irritability of temper, as demonstrated in the passion of anger, is one of the most unhappy of these derangements of our intellect.

The causes of anger are supposed to be these:—*First*, by the law of nature and of society, every one has rights in what he regards as his own property; *second*, one has a right to hold unimpaired whatsoever he can justly acquire in reputation and character; *third*, he has a right to have his feelings respected by others, if he do no wrong to their feelings; *fourth*, he has a right to have the like rights respected in those with whom he is necessarily connected by family and social ties; *fifth*, he has a right to be treated with justice, and according to established laws, by those who are intrusted with power; *sixth*, he has a right to have those who are bound with him in a common subjection to such laws, treated with justice. Whenever any one is offended by the violation of any of these rights, he may be justifiably angry. But in what manner, and to what end he shall express his anger, so as to do himself the greatest justifiable good, is the thing to be known.

Every one who has had a violent fit of anger upon him, knows that it was to himself (independently of the cause and object of his anger) a painful and even a very distressing sensation. No one ever looked back upon such a state of things, as to himself, with satisfaction, but generally with regret, and sometimes with remorse. He feels humbled and grieved in his own estimation of himself. He may too well remember that he used expressions and did acts which he is grieved to have resting in the memory of others or in his own. It is probable, also, that no one ever saw another in a violent passion without feeling that this angry person was degrading himself, and acting more like a brute than a rational being. Whatever be the cause of such anger in another, cool spectators always regard the angry person as under a temporary loss of reason, and in danger of doing some serious mischief, and are prompted to restrain him. Every one feels in such a case that the least that can happen to one so acted upon, and so acting, is that he is preparing for himself hours of self-reproach and of bitterness. If no one likes to remember that he was violently angry himself, and if he is offended in seeing others so, it must be admitted that violent anger is contrary to natural law, as it most certainly is to Divine law. It is an abuse of the trust confided to us to promote our own welfare.

It is consistent with reason for any one who is under the influence of anger to be prepared to ask and answer the question, whether the wrong is real or only supposed, and whether he is himself free from the first imputation of having occasioned by his own error that which he regards as a wrong? If the offence is real, other questions arise of this nature: What real good shall I secure to myself by attempting to get a reparation? and in what respect shall I advance my own welfare by attempting to punish the offender? May I not, in either of these attempts, involve myself by words or acts in some wrong, and give my adversary the advantage of finding me an offender, in trying to vindicate myself? If I could succeed in my attempt, what will it come to? Shall I not make the wrong done to me more notorious, and subject myself to the pity and compassion of others? Is it not better to be silent, and quiet, and leave the offender to time and his own conscience, than to engage myself in a controversy which is sure to be vexatious, and in which I shall run the risk of doing wrong, and

in which I shall not be likely to get any good? If I succeed in humbling my adversary, I shall surely make him my enemy for ever; for, in the nature of man, he is slow to forgive the wounds inflicted on his own self-love. When this matter is over, and time has dissipated the mists which now prevent a clear view of it, and when other feelings and sentiments have arisen, shall I like myself the better for having been silent and quiet, than if I shall have attempted to command justice and to inflict punishment? It is probable that young and ardent minds, and those who are looking back by the light of experience, will answer such questions very differently. But the experienced can tell the young with sorrowful truth, that among the most painful sufferings of life are to be numbered those which have arisen from sudden impulses of anger, expressed in words or acts. The experienced can also tell, with like truth, that in the common occurrences of life, angry words and acts have seldom if ever accomplished the purpose for which they were intended; they have neither obtained justice nor punished the offender; but on the contrary, they have often converted the injured party into an offender himself, and involved him in bitter recriminations, keeping up an irreconcilable aversion, and even enmity, through life. We have so far supposed that a real and justifiable cause of anger existed. But it is in many cases imaginary, especially among young persons. They take up sudden impressions concerning the supposed conduct and words of their associates and acquaintances, when no such conduct or words have occurred; or if any did, none with intention to wound or offend. If there be one case in which an individual feels himself peculiarly and painfully humbled, it is when he has manifested anger towards one who has committed no offence, or who is entirely unconscious of having done so.

It sometimes happens that an offended person can restrain himself from expressions and words when he has been seriously offended. But he cherishes a malicious sort of feeling against the offender, broods over the wrong done, and permits his imagination to inflame the sense of wrong, until he makes himself too unhappy, under this excitement, not to express it in some mode which will occasion pain or affliction to the offender. If there be any one who has fallen into such a condition, he may be asked, whether he knows of anything in the nature of regret or remorse for his own follies and sins, which is so exceedingly burthensome, as to carry about with him the feeling of aversion, ill-will, and malice, towards one who has offended? What, then, is to be done? angry words and acts are forbidden by the law of nature, by self-respect, and by convenience; the memory of an unavenged wrong is intolerable. Is there no remedy? We think there is one in every person's power. If the individual with whom one is at variance can, by calm expostulation, or by mutual friends, be brought to a just perception of the case, that is the remedy. If that fails, there is another; it is of high authority: 'If thine eye offend thee, pluck it out.' Blot such a person from the memory; never permit him to come into your thoughts. Will you pass your life in humiliating bondage to such a one? We say, blot such a one out of your memory. You do him no wrong by that. You do yourself a just and great good: you cut a moral cancer out of your heart.

Among the sources of affliction in human life, is the uncalled-for interference of third persons in the angry collisions of others. It may sometimes be an unavoidable duty to take a part in an angry quarrel. When this duty is to be performed, it concerns every one who is mindful of the trust confided to him of taking care of himself, not to engage in the controversy in such a manner as to become a principal party in it. As a general rule, it is the safe course to let angry persons settle their own concerns as they can. Certainly no one who claims to be regarded as having a discreet sense of his own welfare, plunges himself into a quarrel. Yet this is a very common thing. It is often seen in schools. Parties and divisions grow up, extend, and

become more and more bitter, from the most trifling causes, and are often carried out into manhood, and show their evil consequences through life. This is so because impressions made in that season are very vivid and durable. It is a duty sometimes to take a part in controversies. It must be remembered, when one engages in such quarrel, that one is dealing with persons who are under a sort of derangement, and who are most exceedingly sensitive, and perhaps mutually vindictive. Those who interpose are bound, by the law of self-regard, to interfere with calmness and sound discretion, and so to conduct themselves in word and deed as to do no evil to themselves while they attempt to do all the good possible to the angry parties. On the whole, mismanaged anger is a prolific source of suffering. Yet when calmly looked back upon in a great majority of cases, the cause was some insignificant trifle, magnified into serious importance by angry words and pitiful acts. Such is the propensity of persons to busy themselves in the quarrels of others, that there is little reason to hope that a preventative can be successfully offered to any but to those who have studied out and who reverence the will of the Deity, as disclosed in the nature of things, and in his own positive law.

SELF-RESPECT.

Every one has some sort of opinion, more or less distinct, of all persons with whom he is acquainted. This opinion may embrace intellect, disposition, virtues, vices, personal appearance, deportment, condition in life. So also every one has some opinion of himself on the same, and on many other subjects best known to himself. When one examines his own opinion of himself, he seems to do it as though he were another person. He uses the eyes of others. He turns aside, as it were, by the way, to see himself pass by. The judgment which one forms of himself is often much more unsound than that which he forms of others. The eye cannot see itself; so neither can any one see himself. He must use a mirror. There are many of these. History, books, daily example, his own experience, every person he comes in contact with, are mirrors. If he sees himself in these, and thereby corrects his own errors and follies, and gives himself reasonable and just credit for his attainments, he may come at length to be entitled to entertain a respect for himself. There is a certain best thing to be done, and a certain best manner of doing it, in all possible circumstances in which one may find himself. Nothing is entitled to be considered best which does not conform to natural law, the law of God, the positive law of the land, the conventional laws of society (so far as they are founded in reason and good sense), and to the decencies of life. To that best thing and to that best manner no one perhaps ever perfectly attains; but it cannot be doubted that there is some such standard. He who comes the nearest to it is he who is best entitled to entertain a respect for himself.

PRIDE.

There is a kind of pride which is often mistaken for self-respect. We hear of honourable and of laudable pride. We take pride to be that self-esteem in which a man holds himself. It may be founded in his estimation of the qualities of his mind, in his attainments, in his possessions, in his strength, his beauty, his parentage, and descent. It may also be founded in a consciousness of virtue, and of having faithfully done one's duty in all the relations of life. It seems to arise necessarily from comparing one's self with other persons. If this be the right meaning of pride, it is very clear that it is not always a sentiment which entitles one to respect himself. A man would be thought to be very unwise who should openly declare that he valued himself, in comparison with other men, on account of his wealth, his beauty, or his family connection; equally unwise if he should declare his opinion of himself to be, that he was superior to other men in the gift of natural intellect, in the cultivation of it, or in the practice of the various virtues. The common

sense of mankind, founded in natural reason, does not approve of that self-gratulation which rests on the accident of birth, of inheritance, or even on the acquisition of fortune by one's own industry; nor does it approve of that feeling when founded on qualities which belong to the mind, nor even in the practice of his virtues, unless when manifested in a certain manner. There must be, in the very nature of things, some persons in every community, large or small, who are superior to others in these sources of self-esteem. In every city, town, and village in this nation, there are some persons who are in possession of some of these causes of self-esteem in some comparative degree, and other persons who have the fewest or the least of them. Those who so use their advantages as to entitle themselves to the esteem of others, and who are acknowledged to be respectable for that use, may well be entitled to respect themselves from such causes. Those who use them in such a manner as to announce the feeling of superiority over others, and habitually to offend the watchful feeling of self-love, are properly called the *proud*. It is believed that these views conform to natural law, and to the necessary constitution of human society.

VANITY.

A still greater mistake is made in substituting vanity for self-respect. The word vanity is made out of two Latin words which signify *exceeding emptiness*. It is commonly understood to mean a strong desire to be noticed, considered, and esteemed by others, but on account of things rarely worthy of a rational mind. Vain persons covet praise. They thrust themselves, and all on which they value themselves, upon the notice of others. They delight in recounting their achievements, and sometimes make the sad blunder of speaking to those who know they are mistaken. They touch adroitly on their own excellences, and provoke others to descant upon them. They have such delightful visions of self-complacency, that it seems cruel to disturb them. Such persons are very ready to become tools in the hands of more knowing persons. In general, the display of this poor passion is made by persons of very light and frivolous minds. It is seen at all ages, but strikingly in youth. To see a young person strutting or mincing along in a new garment, or in some personal ornament, and watching to see if he is noticed, and by whom, excites a feeling of pity and contempt. The same feeling arises when young persons are seen, who say in their movements, as intelligibly as though they spoke in plain English, 'Do they not think me very handsome—elegantly dressed—a charming figure—most exceedingly graceful!' In some instances lookers-on do think so, and smile contemptuously at the same time. But in general lookers-on see no such thing as the vain imagine; they do see that which it would be shocking to those votaries of vanity to know is seen. They do see talents wasted, time misspent, foolish hopes, and vain desires. They do see that the purposes of life are misunderstood or perverted. Is there any remedy for these follies? None, probably, unless one would bring home to the minds of the vain that they violate the strongest precept laid down in the code of natural law for the government of persons individually and socially. That precept commands them so to conduct themselves in all things, as to entitle themselves to self-respect, and consequently to the respect of others. If the vain could conceive how small a portion they make of created being, how insignificant a part they make of civilised society, how many there are in that society whose pretensions, if asserted, would be transcendently superior to their own, they might perhaps dismiss their little vanities, and devote themselves to gratifications worthy of their intended nature.

GRATITUDE AND INGRATITUDE.

If a destitute young person should attract the notice of a wealthy man, and should be by him supported, educated, and established in the world, so as to be able to live, to become independent and respectable, every

one would say that this is a case for the feeling and the expression of fervent gratitude. Let us suppose that the patron of this young man frequently reminds him of his former condition, and by what means he finds himself where he is. Suppose the patron exacts a frequent acknowledgment of his bounty, and takes to himself unqualified praise for his goodness. Let us suppose that the obliged party finds his condition very irksome, and almost wishes that he had never been the subject of such burdensome favour, and is at length provoked to say so—*is he ungrateful?* It would seem, then, that gratitude has two sides to it, as well as two parties. He who has conferred a favour has not done all which it concerns him to do; and he who receives a favour may have a difficult task to perform. A bargain is an exchange of one thing for another, and the parties are even. The conferring of favours, whether these be asked for or not, seems to stand on very different grounds. Many elements make up that compound from which gratitude is said to arise. The parties may understand the nature of the favour very differently at the time when it is conferred, and more differently afterwards. He who confers, has a retentive memory; he who receives, a fading one: time engraves the favour deeper and deeper in the former, and wears it out more and more in the latter. In the former, it often preserves the freshness of a new occurrence; in the latter, the sense of favour often goes, and the weight of obligation alone remains. It may be that the complaints made against ungrateful persons are not always well-founded, and that the expectations of those who confer favours are as little so. Some poet has written—

'He that's ungrateful has an only fault—  
All other crimes may pass for virtues in him.'

The meaning of this couplet must be, that the members of society are under no obligations to confer favours, and that, if they do confer them, the party obliged is a monster if he do not—*what?* We know not what is intended, nor that there is any rule by which gratitude is to be manifested. We think that every member of society is to do what of good he can, and to whomsoever stands in need of it. He is not to stop to measure and calculate how he is to be paid for it. He may not be paid by the party benefited directly, but by some other, and in some other and unexpected way. Whosoever confers favours, opens an account with the changes, and chances, and accidents of life. His credit side will look well in the close. If he confer a favour, he does it because he thinks he can and ought to do it. He has the *pleasure* of doing it. If he wishes to avoid the affliction of ingratitude, he has only to avoid letting the party obliged know, unnecessarily, whence the benefit comes. When a favour is done, the party conferring it takes on himself the duty of respecting that feeling of the human heart which is founded in reasonable self-love, and which is entitled to respect—that is, *not to ask one who has had the misfortune to be bound in chains, to clank them for the gratification of him who put them on.* There are cases of extreme ingratitude. They may have been occasioned by the irritating or indiscreet conduct of the party who was entitled to a different return. They are not of common occurrence. When they do occur, uncaused, the disappointed party may hope to find a better subject in his next essay.

SLANDER.

This is a twofold crime: 1. It is a breach of natural law, of Divine law, and of the implied law of society, in relation to the party spoken of; 2. It is a breach of the same law in relation to the party speaking. It has been commonly treated of in the first relation. It is now to be noticed in the second; and if it be shown why it is a breach in this, the other will take care of itself. We beg leave to ask a slanderer a few questions: Do you desire to be esteemed in society for your intelligence, your sense of justice, your knowledge of the decencies of life, and for the observance of them? If you happen to be ill-tempered, petulant, and disagree-

able to your family connections and associates; if you make hasty and troublesome judgments, which you have to rescind or reform; if you happen to be ridiculous in your deportment, and remarkable for silly vanities; are you willing to have these things set forth in any, and every company, by any one who knows of them? Suppose there to be only some slight foundation for some one or more of these things, which, if you could have an opportunity to explain, would be entirely cleared up, are you willing to have that slight foundation made the basis of a structure of reproach, which, if true and real, ought to expel you from decent society? Suppose there to be no foundation at all for any such accusation of yourself, and yet somehow, and unaccountably, it is afloat and circulating, should you not think great injustice to be done to you? This is just what you do to others. You take away their good name, if they deserve to have one; you magnify their little faults and errors, and make them ridiculous or odious; you try them on indictments for serious offences, on which they have no opportunity to defend themselves, and of which they are ignorant. Where did you get your information? What credit were they entitled to from whom you had it? Did you understand them as they meant to be understood? Where and how did your informants learn what they communicated? Were they thoughtless or malicious slanderers like yourself? How much have you added to their slanders by way of recommending and making yourself agreeable? Have you broken any law by this conduct? We take the liberty to answer for you.

You have broken every law which an honest and honourable man, and a rational individual, should respect. 1. You have made every person whom you have spoken to fear you and shun you. You have shown that you know not what the value of a good name is, and have forfeited your own, if you ever had any. You have shown that you are a stranger to self-respect, that you have probably every one of the faults, follies, and errors which you impute to others; and desire to bring them down to your own level. Thus you have broken that law which commands you to do no evil to yourself. 2. You have violated that principle of natural law which commands you to do no injustice to your fellow-men. You know not what opinions you may entertain of the party you have slandered if circumstances (as they may) should bring you into connection with him. You may find him to be, on a better knowledge of him, an amiable and worthy person. You may find all that you have said, and helped to circulate, utterly groundless. If he be one whom you occasionally meet, and even ask to partake of your hospitality, how can you meet him, and manifest towards him every sentiment of respect and esteem, when you have so spoken of him? One of two things must be true—either you *act a lie*, when you meet him in such a manner; or you *speaks a lie*, when you represented him as you did to others. 3. You have broken the law of God. To this law perhaps you are a stranger, and know not what wrong you have done. If so, the kindest thing that any one can do you is, to urge you to find out what it is, and to learn there the sentence of the slanderer.

It may be asked whether one is to be entirely silent at all times, and on all occasions, as to the character and conduct of others? Certainly not. There are many occasions for speaking of others, and for speaking the *truth* of them, whatever that may be. All the members of any community are interested in knowing the true character of each other. The knowledge that this character may be known is one of the most salutary correctives of erroneous conduct, and one of the strongest inducements to pursue that which is commendable. It is probably the case that the members of every community are pretty well understood by all who have an interest in knowing them. We know not of any law which holds it to be immoral to *speaks the truth of any one from good motives, and for justifiable ends*. It is all-important that this principle should prevail in our country, where so much depends on public

opinion. Surely one's arms are not to be folded, and his lips closed, when he sees one bent on mischief, public or private. It may be one of the highest moral duties to declare what men are, and what they are aiming at, in many supposable cases. There can be no surer guide than the *motives* and the *ends*. Inquiries are sometimes made, in matters of greater or less interest, concerning others, confidentially, and where the inquirer needs to be truly informed. The party inquired of has a right to be silent if he thinks he has good reason to be so; but if he answer, he is bound to state the truth. If he chose to speak, and wilfully conceal the truth, so that the inquirer is deceived, he subjects himself to the imputation of an intentional deceiver.

There may be also, and there frequently are, confidential discussions of character, especially concerning public men, and where perhaps there is no particular end in view. This does not seem to be wrong; such intercourse is not founded in malicious or unworthy motives: it is even sometimes instructive and philosophical. This perhaps is the extreme limit. In all other imaginable cases it is probably most consistent with one's own self-respect, and all truly respectable motives, to let other persons alone, and leave to them the care of their own characters.

#### PROFANITY.

Excepting the high crimes which are punishable by the public laws, there is no one so shocking as *profanity*, nor any one which there is so little inducement to commit. Profane swearing is of two kinds:—1. That in which the Deity is called on to do the pleasure of a sinning mortal; 2. That in which the Deity is called on to witness the truth of such a being's thoughtless or wicked declarations. This common practice can be accounted for chiefly on two grounds:—1. Pitiably ignorance; 2. Abominable wickedness. On the first ground, surely the profane swearer must be ignorant of the import of the terms which he uses! If he did understand his own words, he would be struck with horror. Surely if there be any escape for the profane from that condemnation which they imprecate on others, it must be, that mercy will be extended to them in compassion for their ignorance. On the other hand, if they are not ignorant, but do knowingly and wilfully so misuse the gift of an immortal mind, and that unquestionable proof of Divine power and goodness, the *ability to speak*, they cannot be subjects of moral instruction. They should be left, like the consumers of alcohol and tobacco, to shock and to warn others.

Swearing, which formerly pervaded every rank of society, is now to be chiefly found in a very low and uneducated class: it is, in fact, a vulgar and proscribed mode of speech. Nevertheless it is still used occasionally by persons of no humble rank, especially by the young, though chiefly for the purpose of giving an emphasis to speech, or perhaps simply to give token of a redundancy of spirits, and a high state of excitement. To those who are guilty of it for these reasons, it is only necessary to point out that no well-informed person can be at the least less, with the genuine words of the English language, to express all legitimate ideas and feelings, and that to use either profane or slang words is, at the very least, the indication of a degraded taste and an inferior understanding.

Does not one who is habitually profane necessarily entertain a low opinion of himself? Would any respectable merchant, or mechanic, or farmer receive into his service a youth whom he knew to be a profane swearer? Could any one who is known to be such find admission into any school, academy, seminary, or college? Would any respectable parent admit such a one to be a companion of his children, or a visitant in his family? Would not every reasoning person say that a youth who is so ignorant as not to know that swearing is a violation of natural and Divine law, must be ignorant enough not to know that there are many other laws for the proper government of society, and consequently that he is an unsafe person to be trusted? If the profanity be

the consequence of voluntary wickedness, then surely all reflecting persons would say that he who is wicked in this respect is indeed wicked; but then he will be wicked in others also. For as there is one chain which runs through all the virtues, and binds them in a sympathetic union, so also is there a chain which unites all the vices. He who swears may be justly suspected of drinking; he who swears and drinks may be justly suspected of gaming; he who swears, and drinks, and games, must keep very bad company by day and by night. He who keeps such company from such motives must squander his own property, or steal that of somebody else to expend. He who robs another will commit forgery, and he who is so desperate as to commit these two latter crimes will not hesitate long to put a human being out of the way of his pressing wants if he is tempted to do it. It is probable that habitual lying and swearing are the first steps in that mournful series of crimes, and the first beginnings in the course of deplorable wretchedness, which deform and disgrace human society. Will any one maintain that these are necessary evils, and that God has so made man that they cannot be prevented? Surely these are evils wholly of human origin; and where they begin, there also lies the power to extirpate them.

## ENVY.

It is to be kept in view that the main object is to show that this is a good sort of existence if man knew how to use it, and that he is the author of his own afflictions. This is remarkably illustrated in the matter of *envy*. It is probable that a large proportion of mankind, in all classes, suffer from the dominion of this passion. It can be shown that it is peculiarly the passion which man has made for himself out of emulation, which latter is the Creator's work. In this instance, man has been exceedingly ingenious and successful in making himself miserable. He has done worse: he has provided for himself, in creating envy, a fountain which sends forth not one water, but many, and each one foul and poisonous. He who has submitted himself to envy has bound himself to think, to feel, and to act as envy prompts. It would be most shocking to know what agency this monster has had in human affairs. If any one should read history, and watch the movements of his fellow-men, merely to learn the operation of this principle of action, he would see probably the most operative cause of the misery which men inflict upon themselves and on each other. If one has not time to read history, and watch his fellow-men, he may perhaps learn much of what he would find in these authorities by *reading his own heart*.

Envy arises from perceiving in other persons qualities which one's own self-love leads him to wish to have—as beauty, strength, grace, learning, power, &c. It extends to riches, to office, to the respect and esteem in which one is held by his fellow-men, and even to birth and ancestry. It makes one *sorry* that he has not these good things, and makes him *angry* that others have them. One easily persuades himself that great injustice is done to him, in that *he* has them not. The next step is to *hate* him who has them. Then comes the desire to deprive the supposed fortunate possessor of the benefit of them. But to admit that one has these malignant promptings, is contrary to another principle of self-love; and therefore no man tells another of his own envy, and he tries to wrap it up from his own view. As he cannot and dare not openly manifest that he is envious, he must obey the suggestions of malice in the dark. He therefore intrigues, insinuates, and becomes adroit in putting one thing for another; he secretly and by covert means undermines the object of his hatred. He whispers his doubts, suspicions, opinions, and belief. If the tenure of the hated object is too strong to be shaken, then the bad use which he makes of his advantages are sought out. The base accompaniments of his fine qualities are assiduously brought forth, and placed in the strongest light. 'She is beautiful; *but* she is vain, haughty, and silly. He is rich; *but* he got his

wealth by frauds, and hoards it like a miser. He is able, eloquent, and popular; *but* he is selfish and insincere, and would put a yoke on every neck in the country if he could. He is making a great flourish in the world; *but* it is all false and hollow—he came from nothing, and will go back to nothing.' It may be easily inferred that one who has thus surrendered himself to the dominion of envy, not only deprives himself of the profitable use of what he has or might have, but makes himself wretched in contemplating what he must know he cannot have: he is so wrought upon, that whatsoever seeds of crime he may have in his heart are sure to start into luxuriant and dangerous growth.

Can any rational being doubt that this sort of suffering and crime is entirely of man's making? Can it be doubted that he can prevent them? These are violations of natural law and Divine law; and no law comes from this source which cannot be understood and obeyed. Let us take an example, and seek out the unreasonableness and immorality of envy; and to do this effectually, we must take a strong case, and in some degree a fanciful one. Let us suppose that in a seminary of females there is one who is very beautiful; her parents are very rich, and are highly respectable; and that this young lady is distinguished by her genius, and her diligence and good conduct, and is obviously in the receipt of the preceptor's unqualified approbation. Let us further suppose that there are some of her school-fellows who *envy* her. Their countenances show what they feel. Every mark of favour manifested to this fortunate person is a blow on every envious heart. Discontent, distress, and malignity take up their abodes in these hearts, and enter into thriving partnership. But the beauty, the genius, the diligence, the wealth, the parentage, the applause, are not among the dividends which these partners make: these remain where they were: and what dividends do they make? Let us suppose that the envious would do what they would—that is, annihilate the envied qualities, and make the possessor too low and contemptible to be more thought of; and let us suppose, too, that the successful adventurers succeed to what is now the first eminence—is there no one below to pull them down? They are soon down, and by like means; and thus the demolition would descend, until the seminary became too low a place for even envy to find something to live on.

Is not this a fair example of what we continually see in all grades and classes of social life? And is not this passion of envy earth-born, mischievous, and odious? What is the remedy? Common sense and plain reason point out the remedy. Generally speaking, every member in society is just as much in his own place as he is in his own skin. No one can be in another's place. Every one has his place originally assigned to him, and his natural condition in it, by means over which he had no control, and in making which he had no agency. What he will make out of himself, and of the circumstances in which he finds himself, must depend (after the irresponsible state of infancy is passed) on his own thoughts, motives, and acts. He will find his greatest good not in repining at the good of others (which he can never make to be his own, and which he cannot destroy without expecting retributive justice as to himself), but in making his own condition as good as he can, consistently with self-respect and peace of mind. That which is given to others, and all that they can lawfully acquire, is righteously their own. All that is given to one's self, and all that he so acquires, is in like manner his own. If he would have no injustice done to him by those who are below him, he must do no injustice to those who are above him.

## EMULATION.

This has been sometimes classed with envy, but they have nothing in common. One would feel like a culprit in being known to be envious, but would rightly take praise to himself in being emulous. This motive to action was given to man for the best possible purposes; and upon the application of it, with justifiable views,

## THE PRIVATE DUTIES OF LIFE.

and to commendable ends, the advancement of human welfare mainly depends. We understand it to mean, the desire to obtain excellence in laudable pursuits. An envious man may be supposed to say, 'Your eminence distresses me; I cannot bear to see you sitting up there; and though I have not the shadow of hope that I can ascend to your place if you were out of it, nevertheless I must pull you down if I can, and then we shall stand on the same level.' An emulous man may be supposed to say, 'I admit that you are where you should be. You have raised yourself by fair and just means. I have no desire to disturb you, nor to impede your further progress. You have done me no injustice; on the contrary, you have rendered me the important service of showing me how one may honourably rise. I shall follow your example, and endeavour to place myself by your side. If I can get there, we shall have a fair, good-tempered rivalry, and we may animate and quicken each other's efforts. If you are able to keep always in advance of me, you will make me diligent, and enable me to excel others, if I cannot equal you.' There seems to be nothing immoral in this. In this view, emulation is presented in its true and amiable character. Like everything else intrusted to man's use, it may be, and often is, perverted. It frequently excites very unworthy feelings. Hence it has been confounded with envy. It is upon the principle of emulation that diligence in schools is commonly founded; and it is in schools that the perversion alluded to is frequently noticed. When several children are required to get and recite the same lesson, there must be a best and worst among them. That they are such respectively, may depend on natural talent, and upon industry, or on both. It deserves great consideration, whether rewards and punishments are generally understood in their true philosophy. There must be emulation in schools, because there is, and ought to be, that stimulant in all the vocations of life. If men had not the advantage of comparing themselves with each other, and the promptings to exertion which arise from that comparison, this life would be very still and stupid. But what use is to be made of this principle in schools? is a question of exceeding interest.

### PEACE OF MIND.

It is believed that most persons pass a large portion of their lives in a state of inquietude and uneasiness. Persons who have no bodily disease are anxious and disturbed. They have some urgent want which cannot be gratified, or which cannot be so without incurring some evil which would be worse than the unsatisfied want. They have the dread of some probable or possible evil to come, and which is the more terrible because of the uncertainty of the manner and of the time in which it may come. Others are uneasy from remembering the past, in which some benefit was not secured, some blunder made, some wrong done to themselves, some vain gratification not obtained. There are many persons who are habitually discontented. They find everything goes wrong. The weather is bad; their food is not as they would have it; no one does anything in the right time or right manner; or that is done which should not be, or that is omitted which should be done. Such persons are always groaning, sighing, or grumbling. They dislike everybody, and everybody dislikes them; and particularly their abundant *advice* is disliked, and their manner of giving it. There are other persons who are of unquiet mind from more serious causes. They have recollections which distress or torment them. They are transgressors; perhaps criminally so. They have been able to conceal this, but they live in the fear of disclosure; at any rate the fact cannot be hidden from themselves.

These are frightful instances of the agency of this companion which every man has in his own bosom. There are hours in every one's life when he must compare the condition in which he is with that in which he thinks he might have been. To some persons these are hours of dread and terror. It is believed that this

cause of suffering is purely of human origin, and that prevention must be found where the error began. It is the law of the Deity that there shall be such suffering when the guilty mortal makes it necessary to apply that law. There are great differences in the temperament and natural dispositions of persons. It is incredible that the worst-tempered persons would not make a better whole of life, by suppressing their natural propensities, and acquiring a control over themselves, and teaching themselves to look out for what may be pleasant and agreeable (passing by that which seems ill to them), instead of doing exactly the reverse.

There are cases in life in which it is said there must be anxiety and inquietude, from the very condition in which men are placed: persons who sustain public offices, persons who are placed in important trusts, persons whose vocations are perilous, those who are pricked by the thorn of political ambition. It is probable that such persons do experience many painful and distressing emotions, and that they sometimes pay dearly for their distinction; but it is demonstrable that even such persons might have tranquillity if they had a right frame of mind. There are persons who substitute an aching solicitude for the reasonable discretion and care which is all that is required in the performance of duty. There are others who greatly overvalue the distinctions to which they attain or aspire; and very few of them reflect, that when they do succeed, they must take success, especially in popular governments, with the accompaniments of having their worthy acts often misunderstood and reproached, and their mistaken ones magnified and distorted, to suit the occasions of rivals and adversaries.

The remedy for this sort of suffering is within every one's power. Those who are poor, and in humble life, if not in extreme poverty, may possess peace of mind; and it is of easier acquisition by these than by those who are involved in the duties of office, and the responsibility of trust, and the embarrassment of wealth. Certainly, without this treasure, no earthly grandeur, no promise of posthumous glory, is worth having or seeking for. If the laws of nature and the teaching of revelation were properly known, respected, and obeyed, the common causes of inquietude would hardly be known. For example, what is more common than complaints of the weather? It is too hot or cold, wet or dry. It is not nature that mistakes about the weather, but ourselves. The movements of the winds and the waters, and the temperament of both, proceed on some great and universal laws far beyond human perception. That which is exacted of us to believe is, that it is so, and to adapt ourselves to it by our experience and ingenuity. What sort of effect would it produce in the earth if such things were regulated by human perception of what is best? When one has occasion to put to use a board or stick of timber which has been in contact with the ground for a certain length of time, he disturbs and puts to flight families, communities, and whole nations of living beings. Man may be much in the same relation as to general laws (not meant for him to comprehend) in which these insects are on the removal of their covering.

As to all causes of inquietude arising from the operation of nature's laws in which human agency has no concern, they must be right, although they occasion inconvenience to individuals. As to the acts and omissions of others which affect us, some questions are to be asked and answered before one can rightly judge of these; namely, What is the real cause of our complaint? Did not the first fault arise from some act or omission of our own? Do we judge reasonably of the supposed wrong? Do we make charitable allowance for the misapprehension which may affect the party complained of? When the inquietude arises from our own wayward and peevish disposition, from our own misconduct, negligence, or breach of laws, which we could know if we would, the remedy lies in becoming wiser and better, and more reasonable in learning how we may make of life that which it was intended to be,

when we use it as we should. Let any reasonable being look back on his own life, and calmly consider the causes of his own contentions, ill-will, failures, and sufferings in body and mind; how many of these can he fairly lay to the blame of the Creator's laws, of nature's laws, or those of society, whether positive or implied? If to these he can charge but very few, who then but himself is there to take blame for the residue?

We have been trying to show what peace of mind is not. We have to show what it is, or rather in what it is founded. It comes from sober conviction that the Creator has made His own laws for His own universe; that He requires conformity to these laws; that He permits and enjoins the use of what is good and right; that He punishes all that is wrong and disobedient. He has trusted every mortal with his own welfare, but has associated him with others who live in the same trust, each one for his own, but yet for mutual welfare. All are to contribute their common efforts to the common good. Those who have the means are to aid others in acquiring a knowledge of the laws which are common to all. If these laws were understood and applied, how abundantly would peace of mind increase in the world! The schoolboy would get his lessons and obey his preceptor; the labouring-classes would labour diligently, live temperately, and find a greater pleasure in their frugal food than the luxurious in their festivals; for the former live as nature orders, the latter as fashion dictates. The opulent and luxurious would learn that the accidents of their fortune do not exempt them from the laws of nature; that if they have affluence beyond their reasonable and commendable wants, they are blessed with the means of purchasing a precious name; they would learn that no wealth will exempt any man from earning an appetite for his pleasures by physical motion; that if he is tired of being rich and happy, *he must work* to accomplish some reasonable purpose. His distinction is, that he may choose the means in which he will expend to be busy, while others can only work in some prescribed mode to live.

The middle classes, and all who are not dependently poor, have as many and as valuable sources of enjoyment as those have whom they think to be better off than themselves. They can love and be loved; they can be respected and esteemed; they can have the consciousness of behaving well where their lot has been cast; they have a far keener zeal for natural and reasonable pleasure than those who misuse the bounties of accidental condition; they can have peace of mind when it is denied to those whom they deem more fortunate. If these natural laws, which seem to be so plain and obvious, were understood and respected, the labourers in mind, in all their varied employments, would do diligently, and in the best manner in their power, that which they have undertaken. Men of public trust would do honestly, and with a single view to their trust, that which they have undertaken. Suppose it were all so, and yet troubles and disappointments come. This may be, and yet there would be peace of mind. If every one were assured that no act, no omission of his own, makes him suffer, that he has acted faithfully and honestly, and to the best of his ability, in the circumstances in which he was placed, he would be entitled to have, and by the law of immutable justice he would have, *peace of mind*.

#### HAPPINESS.

There is no word in our language more commonly used, nor any one less defined or less understood. It is sometimes taken to mean pleasurable sensations derived through the senses; sometimes it means a peculiar state of mind. It may be said that a pirate who has been brought to the most perfect penitence, and who is sensible that he has forfeited his life to the demands of justice, and that he is about to be transferred from the perplexities and sufferings of this state of being to endless felicity, is *happy* that he is going to be *hanged*. Perhaps it is easier to tell what happiness is not, than what it is. The most perfect *health* is not

happiness, unless one has something to do. Health and riches do not make one happy. These accidents of being rather excite cravings for enjoyment. They are means, not ends. A rich man can ride but one horse, or sit but in one coach, or eat but one dinner, or live but in one house, at a time. Persons in moderate circumstances can do the same.

Health, riches, *power*, and *distinction*, do not make happiness. Distinction is troublesome: it has more pains than pleasures; it is jealous, envious, and distrustful. Power does not make one happy; it demands the most busy watchfulness to keep it. If lost, its absence is often followed by painful suffering, and the possession of it is always accompanied with the fear of losing it. Riches are sometimes regarded as means of enabling one to live in elegant luxury, and even in voluptuous enjoyment. This is no way to be happy; the appetites soon become satiated; the stomach wears out; the senses are palled; diseases come: the body may be racked on a velvet couch as well as on a straw-bed. Is there, then, any such thing as happiness? There must be such a thing, or the laws of nature, which provide for physical, intellectual, and moral being, are false and deceitful, and the gift of revelation is a fable. If there be such a thing as happiness, it will be found in that knowledge of, and obedience to, the laws of nature which make health. It will be found in obeying the propensity to action, to some continuous, useful end; that is, in pursuing reasonably some one of the many vocations in society which tend to secure one's own self-respect and peace of mind, and which tend also to the common good. But there may be disappointments, ill-luck, and causes of mortification and sorrow. These, we apprehend, do not seriously disturb any well-regulated mind, when there is a consciousness that no reasonable foresight or prudence would have discerned and prevented the cause. Perfect happiness in this world, it must ever be remembered, is not to be expected: the only happiness that we can really attain consists in a certain contented tranquillity of mind under all the shocks and changes of this mortal life. There is a point called the *happy medium*; and this should be an aim in all human arrangements. Be moderate in all things. For example, to take no amusement is bad, for it deprives the mind of needful rest and recreation; so likewise it is bad to be altogether given up to amusement, for then all serious objects are lost sight of. The true plan is to take amusement in moderation. Some minds have never awakened to a taste for poetry, fiction, the imitative arts, and music, and they thus lose much pleasure which others enjoy; again, there are some in whom nature has implanted, and use cultivated, so strong a predilection for these things, that it becomes a vice. To be very much in society is sure to deteriorate the human character, making it frivolous, and incapacitating it for taking abstract and elevated views: on the other hand, a perfectly solitary life weakens the mind, lays it open to odd fancies and eccentricities, if not to hypochondria, and ends in some instances by altogether throwing it from its balance. The medium is here also found alone salutary. To be excessively gay, in a world where so many evils lurk around our every step, and so many onerous things call for our attention, is wrong: so is it to be always serious, seeing that the world also contains the materials of much happiness. What is proper is, that we should be ready to rejoice and mourn in moderation on the appropriate occasions. Finally, one may feel assured that if he abide by these moderate desires, and so use his time as to be reasonably busy to some good purpose, and so conduct himself as to be justly entitled to his own approbation, and if he live in the habitual assurance that there is an omnipresent, omniscient, and merciful Judge of moral, accountable, and immortal man, he will certainly be happy.

NOTE.—The matter of this sheet has been extracted, with a few alterations, from the Moral Class-Book of Mr William Sullivan, published several years ago at Boston, United States.

## PUBLIC AND SOCIAL DUTIES OF LIFE.

THE preceding article devoted to this subject embraced the duties which one owes to himself as a rational being. The present is not less important in its character, being intended to point out those duties which we are required to perform with respect to our various public and domestic relations. We begin with our

### DUTIES AS SUBJECTS.

Every civilized nation is governed by some species of authority, for the purpose of preserving order in society. Some governments are good, others are bad; but it does not fall within our province to point out where the ruling authority is injurious, or where it is most advantageous to the people. According to a law of universal application, every independent nation is understood to have the undoubted right to model its government according to its own fancy, genius, or necessities, provided that, in the execution of its plans, it does not wantonly injure its neighbours. Directing our attention to our own country, with which we have here alone to do, we find, as soon as reason dawns upon us in youth, that we are members of a great and enlightened community. We find ourselves subject to laws which were framed long before we were born, and that we must act in a manner not to please our own caprice, but according to the arrangements which have been instituted for the benefit of society at large. But if we thus discover that we are trammelled by certain legal restrictions, not very agreeable perhaps to the wildness of our untamed nature, we likewise find that we possess a great many compensating privileges. While yet opening our eyes to the light, we enter into the enjoyment of all the transcendent privileges of British subjects, and come within the powerful protection of the laws as fully as the oldest and most honoured in the land. It will be perceived that this is a boon of incalculable value. For us armies have fought and bled; for us, in past times, hosts of martyrs and patriots have contended; for us the wisest statesmen and legislators have transacted negotiations securing civil liberty; for us the people who have gone before us have established a variety of the most excellent, the most beneficent institutions. All these things we enjoy without having been put to the smallest trouble. All that we are called on to give in return, as soon as emancipated from the inexperience and ignorance of childhood, is *obedience to the laws*.

A cheerful obedience to the laws is therefore our chief public duty. Possibly some of our laws, from having been framed for a former state of society, or in order to meet particular exigencies, may not now be very judicious in their provisions; yet that forms no solid reason why we should break through them. It is always safer to obey a bad law than to oppose it by violence. Unhappily for some nations, they seem to have no accurate idea of the value of obedience to the laws. When they find themselves aggrieved by oppressive state measures, they are exceedingly apt to break into tumults, and take up arms against the officers of their governments. This is a very shortsighted policy, as the history of all nations proves; for the people are always sure to suffer far more by the coercive measures adopted to restrain them, than they would have done by submitting to the evil they originally complained of. It is the boast and glory of Britain—and long may it be so—that its people know how to respect the laws, even while they consider them to be injurious, and how to correct them by quiet and orderly procedure. In this lies the important secret of their national greatness, their wealth, their public liberty. The advantages arising out of a scrupulous obedience to the laws, consist, in the first place, of social order and quietude, by which the rights of property are

No. 80.

respected, commerce and trade permitted to flourish, and the sacred inviolability of the person preserved. The results of turbulence and civil commotion are—poverty, ruin to property, insecurity of the person, destruction of commerce and trade, and at length military oppression and barbarism. Every intelligent man, therefore, in this country yields not only a bare submission, but a becoming respect to the laws, as well as to the various institutions established by their authority.

Perfect obedience both to the letter and the spirit of the laws does not, however, imply that we should not examine whether they are in every respect answerable to the present condition of society, nor keep us from resorting to legal means to have them corrected, or altogether rescinded. The constitution points out how this is to be done. It is illegal to conspire secretly to overthrow the law. All measures calculated to improve our social condition must be conducted openly and honourably. The means put into our hands by the constitution for improving the law are very powerful, if wielded with discretion. The people have the appointment of the men who constitute the most influential branch of the legislature; if they do not appoint individuals who will meet their views with regard to correcting or abolishing laws, they have themselves to blame: the constitution confers upon them a liberty of choice. It besides gives them the right to present petitions to the legislature, either individually, or in bodies, praying in respectful terms for the amendment or abolition of any law which is deemed oppressive or antiquated. This right gives a vast addition to the power of the people. It is of much greater value than one would at first be inclined to suppose, and is infinitely preferable to the use of violence. The right of petition implies the right of meeting publicly to discuss the propriety of petitioning. This practice of meeting together excites the public mind to renewed efforts in the cause it undertakes. The speeches of the orators are circulated and commented upon by the newspapers all over the country. One meeting gives rise to others, men's minds are enlightened and warmed, and the public opinion acquires by degrees an amount of moral force, any resistance to which would be useless. It is not without reason, therefore, that the people of this country set so high a value on the right to assemble for the discussion of public affairs, and place it in the first rank of their constitutional prerogatives.

Besides yielding obedience to the existing laws, we are under a collateral obligation to be loyal to the sovereign who rules over us. Loyalty is hence another of our chief public duties. There is some difference of opinion with regard to what extent loyalty ought to be carried. It appears to us that this is a simple matter. A power to protect the nation from foreign insult, and to preserve the internal peace of the country, *must be lodged somewhere*. It is found to be most convenient to lodge it in the hands of one person, under proper restrictions. In Great Britain, as will be seen in our history of the constitution of that country (No. 62), it has been placed in the possession of a hereditary prince or king. This person is entitled our ruler or sovereign; we are termed his subjects. Loyalty signifies a fidelity and willingness in serving the king, so that he may be enabled both to protect the nation from outward harm, and to preserve order in society, through the agency of the laws, or, failing them, through the application of force. Seeing that the sovereign is prevented by the constitution from infringing upon the rights of the subject, through the exercise of his power, it is discovered that loyalty is rewarded in the comfort we enjoy; or, to use another expression, self-interest alone, if no nobler sentiment interfere, would lead us to afford

assistance to the king in the execution of his high and important trust. This assistance is demonstrated not only by personal service, if necessary, but by respect. Loyalty may be greatly enhanced by esteem for the private virtues and conduct of the sovereign. When so influenced, it is certainly both an amiable and commendable feeling, and can never, but in ill-regulated minds, degenerate into servile prostration.

In the United States of America, in which the executive is lodged in an elective president, the people call themselves citizens, not subjects; and what we mean by loyalty to the sovereign, they term duty to the commonwealth. It is obvious that there is extremely little essential difference *practically* between these phrases, whatever there may be in *feeling*. The subjects of Great Britain are as free as any people in the civilised world; much freer, indeed, than the inhabitants of France, who disclaim the appellation of *subjects*. These explanations are perhaps useful in admonishing us to beware how we vex ourselves about mere words and sounds. Our duty clearly consists in appreciating the numerous blessings we enjoy in our public and private relations, by whatever name these relations may be called. We are each individually fractional parts of a great nation, whose honour we are called on to sustain through good and bad report. Let us remember that individual virtue can alone promote social happiness, and that social happiness and peace form the basis of political independence. No man can be a good and respectable subject or citizen who is a bad son, a bad husband, a bad father, or a bad master. The nation is but a composition of a great many families, knit together by kindred sentiments and mutual wants; and how can it be great, or worthy of esteem, if its component parts exhibit in their constitution the worst of vices?

Loyalty to the sovereign leads to a subordinate, but important duty. It induces us to respect inferior constituted authorities. All judges, magistrates, or other civil functionaries stand in the light of representatives of the sovereign. The king cannot be everywhere at once, and he deposes these individuals to attend to the wants of his subjects, and to keep good order in society. To show contempt for any court of justice, or for any magistrate, is therefore equivalent to showing contempt for the king himself, as well as for the laws, and is justly punishable. To show our respect both for the laws and the sovereign, we must respect the decisions of judges and magistrates, and support their due execution by our personal influence. Nevertheless it is in every one's power, when they feel themselves aggrieved by these decisions, to appeal to higher authorities for redress; such being the only means allowable by the constitution in opposing the legal power of the established courts of civil and criminal jurisprudence.

A becoming obedience to the laws, and a generous respect for the supreme and inferior-constituted authorities, produces the agreeable result of good order and peace in society. Every one is not acquainted with the different ramifications of the common and statute law; indeed it would be impossible for us to acquire a correct knowledge of these things unless we devoted a lifetime to the study. This difficulty in acquiring a knowledge of the laws has sometimes given rise to a low sort of jeering at our excellent constitution, and it has been represented as cruel to compel an obedience to laws which few can have an opportunity of learning. But this is a fallacy into which we hope our young readers will not fall. The administration of the common law, such as that which applies to inheritance, debtor and creditor, and civil rights generally, rests with a body of educated men, or lawyers, whose services may at all times be commanded. Besides, we may, if we please, purchase digests of these laws for our private amusement and instruction. The other description of law which is made applicable to the preservation of the peace of society, any one can understand, if he have the ability to know right from wrong. We surely all know that it is illegal and criminal to steal, to rob, to murder, to break into our neighbours' houses, or to

attack their persons by violence. It can require no reading of acts of Parliament to understand this. Common sense here serves us instead of legal knowledge.\* Our duty in this matter is very easily defined. We must ever bear in mind that one of the principal acts of duty which the constitution enforces, is the abstaining from meddling violently with the persons and property of our fellow-subjects. In this well-regulated realm, the person of every man, woman, and child is inviolable from private attack. It is a crime almost punishable with the highest penalty of the law to strike any one, either from an idea that they have injured us, or through the influence of passion and prejudice. If we consider that we have been injured, we must apply to the law or the magisterial authorities for redress. We are only permitted to use physical force when in absolute danger of losing our lives or property by violence, there being then no time to apply to the law for protection. It would be gratifying if these regulations were more generally attended to than they seem to be. There are many young men who, from what they are pleased to term a love of fun, but which can be no other sentiment than a love of mischief, or gross ignorance, assail the persons of individuals of both sexes, to their great discomfort, and sometimes serious injury. Now it is clearly illegal to do so, and is generally punished by the infliction of severe penalties by the civil magistrate, though seldom marked with that ignominy which it deserves. Inasmuch as it is held that ignorance of the law does not excuse its infraction, so is it reckoned an invalid apology for the commission of crime to say that you were under the influence of intoxication at the time. Drunkenness is very properly esteemed an aggravation, not a palliation, of the offence.

#### CONDUCT AT PUBLIC MEETINGS.

The right of meeting together publicly to discuss matters connected with our social condition, being so invaluable a prerogative, it is right and fitting that all young men entering into the busy scenes of life should make themselves well acquainted with the rules which have been established by general consent for the proper conducting of such assemblies.

According to usage, a public meeting is not constituted until a person be appointed to preside, or to 'take the chair.' Without this ceremony, the meeting is a tumultuary assembly, or a mob. The first movement is therefore the appointment of a chairman. This functionary, on taking his seat, is for the time supreme in the meeting. His chief duty is the preservation of order. He allows only one to speak at a time, giving the preference to him who has first caught his eye in the act of rising, and giving every speaker a fair hearing. Another of his chief duties is the preventing of speakers from wandering from the subject under discussion; and if they do, he must remind them to keep to the point. In the execution of these and other duties he claims the support of the meeting, and all are bound to yield to his reasonable dictates, and help to maintain his authority. In proportion to the firmness, yet mildness of manner, of the chairman, so is the meeting likely to be well or ill-conducted.

At some public meetings there is no set plan of operations, and a general discussion on the subjects which are brought forward takes place; but at all meetings for specific important objects, there is a previous arrangement among a certain number of individuals to bring forward particular points to be spoken upon. In this case speakers are prepared, and the business assumes the form of the proposal and carrying of a set of resolutions or motions. The following is the routine of procedure:—The chairman having stated the object for which the meeting has been called, an individual

\* At the same time we willingly allow that there is room for great improvement in the dissemination of a knowledge of the statute law, particularly that of a recent date. It is likely that some plan will soon be carried into execution to render the acquirement of such knowledge more speedy and certain.

## PUBLIC AND SOCIAL DUTIES OF LIFE.

steps forward and proposes a resolution for the adoption of the meeting. Whether he enforces the propriety of carrying such a resolution by a speech on its merits, or simply propounds the matter, he must be *seconded* by another individual (with or without a speech), otherwise the meeting cannot entertain his resolution for a moment. If duly seconded, then the motion is fairly tabled. It is before the meeting. After a resolution is proposed and seconded, it is the duty of the chairman to ask the meeting if it be carried or not; if agreed to by a general acclamation, or by an obvious majority, he pronounces the word 'carried,' which settles the point, and the business proceeds by the bringing forward of the other resolutions in the same manner. It is unusual for any member of a meeting to oppose the passing of a resolution, unless he have a better to offer in its stead. If he have, and if he wishes 'to take the sense of the meeting' on the subject, he has a right to be heard. Yet this can only be permitted, provided the meeting has been called in general terms. For instance, if the inhabitants of a town or district generally be called, in order to *consider* of the propriety of such and such measures, in that case every one is entitled to give his opinion, and to oppose the formal resolutions brought forward. But if the meeting be described by advertisement to consist of those inhabitants or others only who agree in the propriety of such and such measures, then no one is entitled to intrude himself on the deliberations who professes opinions contrary to the spirit and end of the meeting. An inattention to this exceedingly delicate point often creates serious heart-burnings and disturbances; and on that account, committees who call public meetings ought to be very particular in the terms of their announcements.

As much regularity is necessary in respect of opposition to motions as in their proposal and carrying. The counter-motion of an opponent is called an amendment, which, to be available, must also be seconded. If not seconded, it drops; but the opposer may place his protest on record; that is to say, if the discussion be in a corporation, or other meeting where books of the minutes or transactions are kept. On being seconded, and discussed by those who wish to speak upon the subject, the matter is brought to the vote by the chairman, but not until both the mover and amender have replied, if they please to do so. After they have spoken, not another word can be uttered, and the vote is taken, a majority carrying. If the votes be equal in number, the casting-vote of the chairman carries. There is another way of suppressing a resolution, which is by 'moving the previous question.' This signifies, to return to the point at which the business of the meeting stood previous to the tabling of the motion; or means, in other words, to do nothing on the subject. But this must also be seconded, and put to the vote in opposition either to the motion or amendment, or to both. The routine is generally to place it in opposition to both; if carried, the matter is settled; if not carried, the order is next to place the motion and amendment against each other, and to take the vote.

Such is an outline of the mode of procedure at public meetings, and it is particularly desirable that attention should be shown to the preservation of regularity. At all public meetings there is a strong tendency 'to go out of order.' By this expression it is meant that speakers are under a constant liability to wander from the point under discussion. They are apt to digress into other subjects, and confuse their auditors; and these, getting impatient, are equally apt to interrupt them, so that a single irrelevant observation may frequently lead to hours of idle debate or colloquy, or 'speaking to order,' as it is termed, and thus the harmony of the assembly be destroyed. Those who attend such meetings should therefore have a regard for the following regulations:—If they speak, they should keep closely to the subject in hand. If they be listeners, they should preserve a strict silence. It is ungentlemanly, not to say disorderly, to utter any sound or make any observation on what a speaker is saying. The speaker

must on no account be interrupted, so long as he keeps to order; and if not in order, it is the chairman's duty to check him. It is likewise disorderly to speak more than once, except in replying before the vote is put, or except it be the rule of the assembly to permit it. Sometimes persons who have spoken rise again to speak as to 'a matter of form.' This is allowable; but in speaking as to form, the merits of the case should not be introduced. On this, however, as on every other point, there is a perpetual tendency to go out of order; hence the absolute necessity for appointing a chairman well acquainted with the forms of public deliberation, courteous, yet impartial, and who has the strength of mind to insist on order being preserved.

At all our public assemblages a certain degree of courtesy is used both among speakers and listeners. On an individual rising to speak, he addresses himself politely to the chairman, and the chairman in return politely mentions the name of the speaker, by which means the audience is made acquainted with the gentleman who is about to address them. When the discussions of the meeting are over, the chairman closes the business with a few observations, and then dissolves the assembly by leaving the chair. When any dispute arises in the course of the business of the meeting upon points of form, it is customary to appeal to the usages of the House of Commons for an example to be followed.

### DUTIES AS ELECTORS.

There are duties of another nature which we may be called on to perform in our character of citizens. We are invested with the high and solemn trust of electing our representatives in Parliament, as well as representatives in our municipal institutions. In the execution of our duty as electors, we are bound to divest ourselves of all factious or personal considerations. We have certainly to consult our own good in making a choice of a representative, but it is only as flowing from the good of the whole community. We must hence act entirely without passion or prejudice. Let us examine the previous habits of life, public conduct, and avowed sentiments of candidates, and calmly consider whether they are such as we can approve of, or as being consistent with the general welfare of the people. We should also recollect that we exercise the trust of electors for many who do not possess that privilege. A large proportion of the community consists of women and children, persons in a humble condition, the sick, and the helpless. These look to us for protection from wrong, and it is our duty to afford it to them. If we therefore act with levity and imprudence in appointing men who, from their conduct and character, are unfitted to exercise the important function of public representatives, we in more ways than one commit a crime against society, and prove ourselves unworthy of possessing the valuable prerogatives with which we have been invested by the constitution.

In our capacity as citizens we are frequently called upon to elect representatives in different municipal bodies; such as civic managers of the city in which we reside, managers of local trusts—general, political, and religious. There is often much heat at such elections; a petty factious spirit frequently governs the choice which is made: sometimes the meanest passions of our nature are exhibited during the contest. The observations we have made on our duties as electors generally, apply here with peculiar force. As those who present themselves as candidates live amongst us, we can never find any difficulty in estimating their character and qualifications. But we must take care not to be borne away by private feelings; we must not give our vote simply because the candidate is an acquaintance. A consideration for *what is best for the public interest* should in every case govern us; and we should not be afraid to let these our sentiments be known, for they can give no honourable man offence. But even after we have made choice of the individual whom we intend to support, from a conscientious conviction that his election would prove beneficial to the whole community,

we ought not unduly to influence the suffrages of others. They may be convinced that another candidate possesses higher qualifications for, and a superior claim to, the office; and it should never be lost sight of that their opinion is entitled to equal respect with our own. We ought not, therefore, by intimidation, or by the exercise of any undue influence, which, from our position in society, we may possess over others, to coerce them into the support of an individual to whom they may be conscientiously opposed. Were this rule to be universally adopted, there would be an end of those disgusting exhibitions by which too many election contests are disgraced. We may, indeed, legitimately endeavour to convince our fellow-electors of the erroneousness of their opinion, but we have no right to ask them to act in opposition to it.

In all cases of election of members of civic corporations, and such-like bodies, the chief merit in candidates, after that of good and respectable character, is soundness of judgment, and after that, activity of habits. The power of fine speaking, or eloquence, is not required in such a functionary, and should be esteemed very lightly. That which is required is a power of thinking coolly, an integrity of purpose, and a willingness and ability in taking a share of the burdensome duties to be performed. Our qualifications as electors perhaps render us liable to be ourselves elected. In the event, therefore, of being called forward by our fellow-citizens to fill the honourable situation of their representative, it is our duty to sacrifice perhaps our own feelings and a portion of our time in the public service, provided we conscientiously consider ourselves qualified for the task, and that our health and private circumstances permit it. The principal question we have to put to ourselves, when we are so brought forward, is, 'Have we sufficient time to spare to attend the various meetings—to sit and deliberate in the numerous committees—to have our minds frequently occupied with public affairs?' If we deceive ourselves in answering this important question, we wrong society, and give ourselves cause for much after disquietude. Is it, or not, the proper way for every one who is worthy of this trust, calmly, deliberately, and to the best of his knowledge and belief, to do those acts which will best preserve for his own use the beautiful fabric of our political institutions? If he perceives and rejoices in the good which he and others derive from it, will he not best perform his duties to those who come after him, to use it, and not abuse it, that they may have the like good? Little suggestions of selfishness, rivalry, and petty local interests, and, most of all, perverted and mischievous ambition, are the blocks over which citizens are apt to stumble and fall, in the otherwise luminous and clear path in which they are permitted to move.

#### DUTIES AS JURORS.

The laws under which we live give us the invaluable privilege of trial by jury; in other words, we are tried for the commission of offences by a body of men chosen indiscriminately, as nearly as convenient, from the class of society in which we have moved. By such a considerate regulation there can be little risk of individual oppression, provided those who compose juries do their duty. It is therefore incumbent on citizens who are liable to serve in juries, to make themselves acquainted with what is understood to be their duty when so called upon. It requires no learning to fulfil the character of a juror. It requires no more than a coolness of thinking, and a mind above being carried away by prejudices or feelings. The juror is to remember that it is the jury which is the judge in the case, not the judges who sit on the bench. Keeping this in view, it is one of the chief qualities requisite in a jury to maintain its proper dignity and honour inviolate, nevertheless with all courtesy, and to act with firmness in the execution of its important function. Besides deliberating dispassionately on the evidence presented, it is the duty of the juror to be totally regardless of every consideration but

that of justice. He is neither to regard the rank of the culprit nor of the injured party. In a court of jurisprudence all men sink to an equality. It is also the duty of the juror, after forming his conscientious opinion, not to be coerced, or flattered, or spoken into a different opinion. He is invested with a solemn trust, and that trust he must preserve with scrupulous care, as consonant with the best interests of society.

#### DUTIES AS NEIGHBOURS.

Besides the duties which we have to perform as members of a great nation, we have duties of a similar nature to perform as inhabitants of a town, district, or neighbourhood, and in relation to which we sometimes receive the appellation of citizens. Every person belongs to a neighbourhood, which is both local and social. Even those who have removed into new countries, and who dwell in solitary abodes, do not lose the sentiment of neighbourhood. The nearest person to them is a neighbour, though separated by long distance. And when this sentiment cannot be preserved in fact, it may be in thought, and by that means it usually is so. Perhaps the last impressions that leave the heart of one who has wandered into far distant regions, are those made in his early days, in his native home. In general, as every one lives in a neighbourhood more or less dense, he can promote his own happiness, and that of those around him, by observing a becoming moral conduct. He has a right to enjoy life, and to use all things which he has, to that end; but he has not a right to any enjoyment which necessarily disturbs that of others. Peace, tranquillity, and security within one's own walls, is the main purpose of life. No one has a right to interfere in these things but by order of the public law. A neighbour, therefore, who so conducts himself, and those means of pleasure which he commands, as to vex, harass, and disturb those who are necessarily within sight, hearing, &c. commits an offence against morality. It often happens to be the pleasure of one who dwells in a dense neighbourhood to keep one or more animals, whose habitual noises disturb those who necessarily dwell within hearing, in the hours allotted to repose, and frequently when persons are visited by sickness, and when any noise is distressing. Now, whatever the rigid law of the land may say in such cases, the law of morality says that the suffering party has an unquestionable right to remove his trouble, if the proprietor of the cause of such nuisance will not, on request, remove it himself. A more peaceable way would be, to have it removed by order of the public magistrate. Many of such petty nuisances ought to be removable on summary verbal application to the proper authorities, and not in the slow, written, and printed process in which the movements of ordinary law are commonly made.

The moral duties of neighbourhood extend to all things which minister to the common comfort, convenience, and security. Each one of a neighbourhood is bound to make his own dwelling-place as agreeable and pleasant to those around him as he reasonably can. Each one is morally held to uphold and sustain a good name for his own little community. He is therefore to join, with a liberal and manly feeling, in all the improvements which tend to please and adorn. Such things, even if they occasion some expediture, are sources of self-satisfaction; and one comes at last to take an honourable pride in hearing his street, his village, his town or city, commended by observers.

There is another sort of neighbourhood which is founded in social intercourse, and in the interchange of visiting and hospitality. As the world now is, this is commonly regulated by artificial and somewhat unnatural rules. It is often ostentatious, luxurious, and destitute of all feelings and thoughts in which well-trained moral minds can take pleasure. A profuse and voluptuous entertainment, comprising food little adapted to promote health and vigour, and in quantity sufficient for ten times the number, that rather look at than consume it, is an unsatisfying way of being happy in social

intercourse. There are modes of maintaining such intercourse, which are innocent, pleasing, and dutiful. Mankind are fitted for such. The interchange of friendly visits, for conversation, music, and rational amusement, with such things as may be used without suffering, or impairing health, is that kind of neighbourhood (in such relations) which is permitted and enjoined. We have, however, little reason to think that intimacies of this sort are likely to meet with such consideration as would induce the further extension of them.

Every person, in general, is a member of some kind of society or association. Some persons belong to many. These are intended for some useful purpose. Every one who is such member has some duties to perform. He owes some proper part of his time, some proper contributions, to the common object, and has an interest in the prosperity of the design. All these institutions do some good, and some of them eminent good, in helping on the great purpose of social life, which is general improvement. Of this nature are public charities, educational institutions, libraries, agricultural societies, and those for suppressing intemperance and immorality. No well-disposed citizen can conscientiously abstain from giving his aid and support to such objects. It is each one's duty to try to leave the world a little better than he found it. No one can say these are matters which do not concern him. Suppose every one should say so, and had said so from the beginning, society would still be made up of barbarians. Every good that is done in any community affects, directly or indirectly, every member of it. The law of example, of imitation, of doing as others do, has a most pervading and astonishing influence. Every community may be likened to a vessel full of water; no one drop in it can be moved without affecting every other drop.

#### DUTIES IN OUR DOMESTIC RELATIONS.

**Marriage.**—This institution is agreeable to a law of nature, and is an ordinance of the Creator. There are profligates who have doubted this; but they have exhibited no reason on their side. It is obvious that man is not only a gregarious, but a pairing animal. Marriage is consistent with the finest of his feelings—the most noble of his faculties. It began when man began. It is ordered to perpetuate the succession of the human family. It is ordered for the whole duration of adult age. It is man's peculiar privilege in this; it connects him with generations which are gone, with that which is passing away, and with those which are to come. The memory and the ashes of the dead are precious to him, and no other animal has that sentiment. He alone contemplates that his own memory will be held in honour, and that the place of his earthly quiet will be sacred. He only is enabled to conceive that moral and physical wrong will bear his own stamp in the character and in the frame of those that follow him; he only knows that a good name may be an honourable inheritance. These are the sentiments which spring from the beneficent gift of marriage. However much one may misunderstand or abuse this gift, nature, ever faithful to her trust, forces these sentiments on the heart.

Marriage is recognised as a contract of a binding nature in all civilised nations. By some it is considered, from its solemnity, to be of a sacred character; by others it is deemed only a civil bond of connection. All, however, agree in holding it to be an irrevocable contract. The laws of the land, those of nature, and the Divine law, disclose the sentiments, the feelings, and the awful sense of duty with which this undertaking should be regarded. Yet it is frequently entered into from motives highly reprehensible, and sometimes with shocking thoughtlessness. It is from such causes that we too frequently see this sacred union, which should be the true source of the highest human happiness, become that inexhaustible fountain from which both parties are daily and hourly compelled to drink, and from the same cup, the bitterest waters.

In a great number of instances, marriage is contracted with exceedingly little regard to the qualities of

the mind on either side, particularly on the side of the man. If one could penetrate the ear of an enamoured youth, some good might come from such suggestions as these:—Do you know what will come of that engagement which you are about to make? Are you about to tie yourself by bands, absolutely indissoluble while you live, to a mortal who has feelings, wishes, wants, hopes, and fears, which must become yours, and a part of your very self; or which you must resist, control, or contend with? Do you know that pain, suffering, and sorrow, originating in either, must be borne by both? Are you aware that whatsoever of error, folly, or crime, may be chargeable to either of you, or to any who may spring from your contract, will be your common burthen and shame; and that from those you can relieve yourself nowhere but in the grave? Or, do you know that this attractive being will be your kind friend; your counsellor; the welcome soother of your cares and anxieties; the generous and charitable judge of your infirmities; the inspirer of honourable ambition; your fellow-labourer in joint interests; the ornament of your life; the gracious, considerate, faithful, gentle companion, who will make your own virtuous home the place to which you refer all earthly happiness? Who, it may be asked, that is 'in love' has leisure or inclination to think of such trifles as these?

There is no reason why the passion of love should be wrapped up in mystery, nor any why the mind should be stained in considering its nature. It would prevent much and complicated misery in the world if all young persons understood it truly. There are in every human being seeds, each one of which may be made to germinate, and may be so cultivated as to produce the most odious vices, or the most serene and heavenly virtues. There is in every human heart a fund of kindness, tenderness, and affection, which makes itself known to be there in due time. It demands to be applied. This is the trying and perilous moment in youthful life. There is some one, somewhere, who will take that fund, and give back its full equivalent. The external senses and the heart are in search of that one. Happy will it be for the searcher if he will take reason as a monitor to keep the senses and heart in order. But reason is commonly regarded not as a kind and faithful friend, whose duty it is to whisper, 'Begin nothing of which you have not well considered the end,' but as a withered scowling matron, who, being utterly dead to the impulses of youth, denies that there ought to be any. If there has been no preparation for this eventful period; if the mind has not been enriched with the teachings of rational prudence; if the eye has not been taught to distinguish between the real and the fictitious; if the ear has not learned to discriminate the meaning of sounds; if life as a whole, if the consequences of irrevocable deeds be not thought of, there is peril; and the pure drop from the fountain may flow into any sea but that of happiness. In seeking for that being who is to be a companion during life, one grievous failing must be avoided. Young men frequently amuse themselves by playing with the feelings of young women. They visit them often, they walk with them, they pay them divers attentions, and after giving them an idea that they are attached to them, they either leave them, or what is worse, never come to an explanation of their sentiments. This is to act the character of a *dangler*, a character truly infamous. Young men cannot, indeed, be too cautious in the attentions which they bestow on unmarried females, who on their part should be equally guarded in not encouraging the addresses of any individuals whom they would not choose to marry.

According to the present state of society, one of the influential counteracting elements to marriage is, or ought to be, a high degree of prudence. No one ought to marry who cannot foresee that he will be able to support the additional expenses of a wife and family, and at the same time fulfil his other necessary obligations. By good management, these additional charges are not great, but they amount to something, and he is worse

than an infidel who does not provide against them. We are of belief that every industrious, active, and sober man will find no serious obstacle in this respect. It is from idleness, love of company, and intemperance, not from simple expenditure on family necessaries and comforts, that ruin and poverty in the married life are produced. The dread of encountering the expenses of a family, though acting as a salutary check on imprudent marriages, is frequently productive of many gross vices, tending to the injury both of individuals and of society. Celibacy, especially when circumstances would permit marriage, is not respectable; it is considered akin to vagrancy. He who marries and settles down as a householder, meets with the approbation of the world. Why is this? it may be asked. Because in marrying we give a guarantee to society for our good behaviour. It is not to be doubted that a young, well-educated, industrious couple, who are sincerely and affectionately attached, on a sober examination and conviction of each other's worth and suitability to each other, may be happy with means far short of the fashionable standard. Presuming that such a couple are wise enough to take life for the real and substantial good that it can produce—and as a whole, it would do them great injustice to suppose that they could not find that good in a small, simple, cheerful, tranquil mansion—it would be doing the friends of such a couple the like injustice to suppose that they could not visit them, and be satisfied to see them happy through such means.

According to the usages of society, it is the custom for the man to propose marriage, and for the female to refuse or accept the offer. There ought to be a perfect freedom of the will in both parties. To impose any species of constraint on either party is most mischievous; it would be a gross violation of our most sacred privileges. Both parties, therefore, ought freely to think for themselves, however much they may seek the advice of those who are inclined to afford them counsel.

In treating of this subject, it may be of service to offer a few special advices to young women. Our first recommendation is, that they ought to be in no haste to accept a lover. Let them know him a sufficient time to judge of his qualities of mind, temper, habits, &c. before they allow themselves to be inveigled into a marriage with him. Far better for them to remain single, than heedlessly incur the risk of being miserable during the remainder of their lives. In general, young women are much too anxious to involve themselves in this respect. The following observations on the injurious effects of making marriage the sole object of a young woman's thoughts, occur in a popular work by Mrs Farrar, and are well worth attention:—

“Some one has said, that “matrimony is with women the great business of life, whereas with men it is only an incident”—an important one, to be sure, but only one among many to which their attention is directed, and often kept entirely out of view during several years of their early life. Now this difference gives the other sex a great advantage over you; and the best way to equalise your lot, and become as wise as they are, is to think as little about it as they do.

The less your mind dwells upon lovers and matrimony, the more agreeable and profitable will be your intercourse with gentlemen. If you regard men as intellectual beings, who have access to certain sources of knowledge of which you are deprived, and seek to derive all the benefit you can from their peculiar attainments and experience—if you talk to them as one rational being should with another, and never remind them that you are candidates for matrimony—you will enjoy far more than you can by regarding them under that one aspect of possible future admirers and lovers. When that is the ruling and absorbing thought, you have not the proper use of your faculties; your manners are constrained and awkward, you are easily embarrassed, and made to say what is ill-judged, silly, and out of place; and you defeat your own views by appearing to a great disadvantage.

However secret you may be in these speculations,

if you are continually thinking of them, and attaching undue importance to the acquaintance of gentlemen, it will most certainly show itself in your manners and conversation, and will betray a weakness that is held in especial contempt by the stronger sex.

Since the customs of society have awarded to man the privilege of making the first advance towards matrimony, it is the safest way for woman to leave the matter entirely in his hands. She should be so educated as to consider that the great end of existence—preparation for eternity—may be equally attained in married or single life, and that no union but the most perfect one is at all desirable. Matrimony should be considered as an incident in life, which, if it come at all, must come without any contrivance of yours; and therefore you may safely put aside all thoughts of it till some one forces the subject upon your notice by professions of a particular interest in you.

Lively, ingenuous, conversable, and charming little girls, are often spoiled into dull, bashful, silent young ladies, and all because their heads are full of nonsense about beaux and lovers. They have a thousand thoughts and feelings which they would be ashamed to confess, though not ashamed to entertain; and their preoccupation with a subject which they had better let entirely alone, prevents their being the agreeable and rational companions of the gentlemen of their acquaintance which they were designed to be.

Girls get into all sorts of scrapes by this undue preoccupation of mind; they misconstrue the commonest attentions into marks of particular regard, and thus nourish a fancy for a person who has never once thought of them but as an agreeable acquaintance. They lose the enjoyment of a party if certain beaux are not there whom they expected to meet; they become jealous of their best friends if the beaux are there, and do not talk to them as much as they wish; every trifle is magnified into something of importance—a fruitful source of misery—and things of real importance are neglected for chimeras. And all this gratuitous painstaking defeats its own ends! The labour is all in vain; such girls are not the most popular; and those who seem never to have thought about matrimony at all, are sought and preferred before them. We may add the advice, that young women should not consider it a serious misfortune even if never married: there is nothing disreputable, while there may be much happiness, in the condition of an old maid.

#### HUSBAND AND WIFE.

Marriage having at length taken place between two parties who feel a reasonable hope of being happy together for life, each has entered on a condition requiring the exercise of particular duties. These we shall endeavour to narrate, commencing with advices

To *Husbands*.—1. Always regard your wife as your equal; treat her with kindness, respect, and attention; and never address her with the appearance of an air of authority, as if she were, as some misguided husbands appear to regard their wives, a mere housekeeper.

2. Never interfere in her domestic concerns, such as hiring servants, and the like.

3. Always keep her properly supplied with money for furnishing your table in a style proportioned to your means, and for the purchase of dress, and whatever other articles she may require, suitable to her station in life.

4. Cheerfully and promptly comply with all her reasonable requests and wishes.

5. Never be so unjust as to lose your temper toward her, in consequence of indifferent cookery, or irregularity in the hours of meals, or any other mismanagement caused by her servants; knowing the difficulty of making many of them do their duty.

6. If she have prudence and good sense, consult her in all great operations involving the risk of very serious injury in case of failure. Many a man has been rescued from ruin by the wise counsels of his wife; and many a foolish husband has most seriously injured

himself and family by the rejection of the advice of his wife, stupidly fearing, if he followed it, he would be regarded as henpecked! A husband can surely never consult a counsellor more deeply interested in his welfare than his wife.

7. If distressed or embarrassed in your circumstances, communicate your situation to her with candour, that she may bear your difficulties in mind in her expenditures. Women sometimes, believing their husbands' circumstances better than they really are, disburse money which cannot be well afforded, and which, if they knew the real situation of their husbands' affairs, they would shrink from expending.

8. Never on any account chide or rebuke your wife in company, should she make any mistake in history, geography, grammar, or indeed on any other subject. There are, I am persuaded, many wives of such keen feelings and high spirits (and such wives deserve to be treated with the utmost delicacy), that they would rather receive a severe and bitter scolding in private, than a rebuke in company, calculated to display ignorance or folly, or to impair them in their own opinion, or in that of others.

*To Wives.*—1. Always receive your husband with a cheerful countenance—leaving nothing undone to render home agreeable—and gratefully reciprocate his kindness and attention.

2. Study to gratify his inclinations in regard to food and cookery; in the management of the family; in your dress, manners, and deportment.

3. Never attempt to rule, or appear to rule, your husband. Such conduct degrades husbands—and wives cannot do otherwise than partake largely in the degradation of their husbands.

4. In everything reasonable comply with his wishes with cheerfulness and promptitude—and even, as far as possible, anticipate them.

5. Avoid all altercations or arguments leading to ill-humour, and more especially before company. Few things are more disgusting than the altercations of the married when in the company of friends or strangers.

6. Never attempt to interfere in his business, unless he ask your advice or counsel; and never attempt to control him in the management of it.

7. Never confide to gossips any of the failings or imperfections of your husband, nor any of those little differences that occasionally arise in the married state. If you do, you may rest assured that, however strong the injunctions of secrecy on the one hand, or the pledge on the other, they will in a day or two become the common talk of the neighbourhood.

8. Try to cultivate your mind, so as, should your husband be intelligent and well informed, you may join in rational conversation with him and his friends.

9. Regard nothing as light and trifling, that may produce even a momentary breach of harmony, or the slightest uneasy sensation.

10. If your husband be in business, always, in your expenditures, bear in mind the trying vicissitudes to which trade and commerce are subject; and do not expose yourself to the reproach, should he experience one of them, of having unnecessarily expended money of which you and your offspring may afterwards be in want.

11. While you carefully shun, in providing for your family, the Scylla of meanness and parsimony, avoid equally the Charybdis of extravagance.

12. If you be disposed to economise, I beseech you not to extend your economy to the wages you pay to seamstresses or washerwomen, who, particularly the latter, are too frequently ground to the earth by the inadequacy of the wages they receive. Economise, if you will, in ahaws, bennets, and handkerchiefs; but never, by exacting labour from the poor without adequate compensation, incur the dire anathemas pronounced in the Scriptures against the oppressors of the poor.

*To both Parties.*—1. Should differences arise between husband and wife, the contest ought not to be, as it unfortunately too frequently is, who shall display the most spirit, but who shall make the first advances, which

ought to be met more than half way. There is scarcely a more prolific source of unhappiness in the married state than this spirit, the legitimate offspring of odious pride and destitution of feeling.

2. Perhaps the whole art of happiness in the married state might be compressed into two brief maxims—"Bear and forbear;" and "Let the husband treat his wife, and the wife her husband, with as much respect and attention as he would a strange lady, and she a strange gentleman."

3. I trust much caution is scarcely necessary against flirtations, well calculated to excite uneasiness, doubts, and suspicions in the heart of the husband or wife of the party who indulges in them, and to give occasion to the censorious to make sinister observations; for it is unfortunately too true, that the suspicion of misconduct often produces fully as much scandal and evil as the reality.

It is a good rule of reason and common sense, that we should not only be, but appear to be, scrupulously correct in our conduct. And be it observed, that, however pure and innocent the purposes of the parties may be at the commencement, flirtation too often leads to disastrous results. It breaks down some of the guards that hedge round innocence. The parties in these cases are not inaptly compared to the moth fluttering around a lighted candle, unaware of the impending danger. It finally burns its wings, and is thus mutilated for life. "He that loveth the danger, shall perish therein." "Lead us not into temptation" is a wise prayer; and while we pray not to be "led into temptation," we most assuredly ought not to lead ourselves into it. I know these remarks will be charged to the account of prudery; but, at the risk of that charge, I cannot withhold them.

4. Avoid all reference to past differences of opinion, or subjects of altercation, that have at a former day excited uneasiness. Remember the old story of the blackbird and the thrush. "I insist it was a blackbird." "But I insist it was a thrush," &c.

The preceding rules, if as closely followed as human imperfection will allow, can hardly fail to secure happiness. And should only one out of every ten readers profit by them, I shall be richly paid for their concoction. I cannot conclude this essay better than by adding the following admirable advices of Julia de Roubigné to her daughter, shortly previous to her death:—

"Sweetness of temper, affection to a husband, and attention to his interests, constitute the duties of a wife, and form the basis of matrimonial felicity. These are, indeed, the texts from which every rule for attaining this felicity is drawn. The charms of beauty, and the brilliancy of wit, though they may captivate in the mistress, will not long delight in the wife. They will shorten even their own transitory reign, if, as I have seen in many wives, they shine more for the attraction of everybody else than of their husbands. Let the pleasing of that one person be a thought never absent from your conduct. If he love you as you would wish he should, he would bleed at heart should he suppose it for a moment withdrawn; if he do not, his pride will supply the place of love, and his resentment that of suffering.

Never consider a trifle what may tend to please him. The greater articles of duty he will set down as his due; but the lesser attentions he will mark as favours; and trust me, for I have experienced it, there is no feeling more delightful to one's self than that of turning these little things to so precious a use.

Above all, let a wife beware of communicating to others any want of duty or tenderness she may think she has perceived in her husband. This untwists at once those delicate cords which preserve the unity of the marriage engagement. Its sacredness is broken for ever if third parties are made witnesses of its failings or umpires of its disputes."<sup>24</sup>

\* The above excellent admonitions are from an American work called the 'Philosophy of Common-Sense,' by Mr Carey.

## FAMILY RELATIONSHIP.

The marriage state is the foundation of one of the most sacred and important institutions in society—that of a family. A family is a little commonwealth, jointly governed by the parents, but under the more special guardianship and direction of the husband and father, who is morally and legally the *head of the house*. To the father the children naturally look for protection, subsistence, advice, example, and encouragement. The father, therefore, has a serious obligation to perform in the proper rearing of his children. He is bound to educate them according to his means, to support them till they are able to depend on themselves, and to have them taught a business, or put in some other fair way of gaining an honest livelihood. It is also incumbent upon parents to avoid all unseemly partialities towards the different members of their family. The system of favouritism, however, is a mistake into which individuals with the best intentions, and of the most amiable dispositions, are very apt to fall. It is seldom, indeed, that all the children of the same parents are possessed of the same docility, sweetness of temper, and those other qualities which are best calculated to attract and rivet the affections of those who have occasion to be brought most intimately into contact with them; and it is therefore very natural for parents to become more peculiarly attached to those who appear to possess these qualities in the highest degree. This partiality, however, is very frequently entertained towards those who are least deserving of it, but who have the cunning to make themselves appear in the eyes of their parents more amiable than their brothers and sisters. But whatever may be the foundation of it, it is an act of gross injustice to the other members of the family; for they are all equally entitled to parental tenderness and affection. Besides, this partial treatment has a natural tendency to engender strife and animosity among the children themselves. The pet of the parents will seldom prove the favourite of those members of the family who have been unjustly neglected; and who will therefore naturally feel disposed to resent their ill-usage upon the usurper of their rights, as well as to murmur and complain against the injustice itself. The children, on the other hand, are bound to obey their parents, and to exert themselves to make them happy.

Parents are sometimes grievously distressed in consequence of the bad behaviour of their children. Their reasonable hopes are disappointed, their best feelings are tortured. An idle, ungrateful, dissolute son, is such a complicated cause of suffering, as may, if anything may, lead one to murmur at the order of things. It may be admitted that such a parent is very likely to break out with complaints against the world. This suffering, however keen and biting it may be, is not a natural, but a moral evil. There is a moral wrong somewhere. Is it in the parent himself? Has he watched the beginning of error, and drawn his child off from the descending plane? But perhaps the downward course has been long begun upon, and art and deceit have made such progress, that the child has been able to elude parental inquiry. This can hardly happen with a watchful parent while his child is under his own roof. Perhaps the downward course has been begun upon when a child is at a distant school, college, or in a place of business, preparing for manhood. If a parent has placed a child where he cannot superintend him, or with those who do not undertake to do this, or who will not if they do, the parent is not excused because others are in fault. A child who is sent away from home is, as the world is now constituted, always sent into some hazard. The hazard is, when least, that the preceptor, guardian, and master may be deceived. The seductions may be such as to plunge a boy into ruin, even before those who see him daily, and who mean to do their duty, have the least intimation of it.

Evils, such as are here alluded to, may be in some measure unavoidable in the present imperfect condition of society; still a parent ought to do all in his power to

obviate them by implanting good habits in his children. It would be well, for instance, if fathers of families would endeavour to give their sons a taste for such a judicious course of reading as would lead them from the contemplation of vicious objects of pursuit. If they do so, and put them in a right bias, they may depend on them acquiring a great deal more useful knowledge after they leave school than they could possibly have learned there. Nearly all the men who have distinguished themselves in the world are found to have acquired their knowledge through private desultory study after leaving their classes; and many, in their autobiographies, trace their good fortune to the taste for reading given them by their parents.

A family of children usually consists of the two sexes. There are brothers and sisters. The intercourse which takes place between these parties ought to be of the most friendly kind. They should strive, by mutual assistance and advice, to make each other happy. In many instances, these relations make a very great mistake as to the real good of life, in not cultivating a cordial and affectionate friendship with each other. In early life they are apt to be in each other's way, and to have irreconcilable wants; thus they very soon fall into alienations. They cannot, however, shake off the laws of nature. They must have an interest in each other whether they will or not, and it will essentially promote their mutual welfare to have a kind and gracious one. The common causes of their differences are exceedingly insignificant, and often contemptible. They will see the day when they will so think of them. The time presses hard upon them when they will need counsel, support, and some one to care for them in a manner which none but brothers and sisters can do. When all has gone on well from the cradle upwards among such relatives, they become to each other not only the most useful friends, but the most agreeable companions. They are the natural confidants, when it would be folly to trust any one whose sympathy and solicitude may change. Brothers and sisters, who are thus bound together by affection, sometimes hazard the connection by volunteering friendly, but very unwelcome, commentaries and advice. This is a very delicate matter. Giving unasked advice on any occasion requires very great discretion. If one sees that his brother is blundering, there are many modes of so approaching him as to lead him to find that he needs advice, and of putting him in search of it. If there be a right understanding, he will go where he is sure of having the best and the sincerest. To assume a dictatorial authority over a brother or sister, is to inflict a wound on self-love which is not readily forgiven. We have already noticed the value of civility and politeness between such near connections; and we add, that sincerity and truth are nowhere more profitable and necessary. 'Familiarity breeds contempt' is a true saying, and is very apt to find an application of its truth not only in the intercourse of brothers and sisters, but in that among more distant relations. We beg to warn all classes of relations who frequently meet together, against using too much familiarity, against using too little ceremony, against taking liberties with each other. Let them preserve towards one another the most respectful, yet friendly terms, if they wish to avoid falling into differences. Let them remember that the quarrels of relations are almost irreconcilable, and that even when forgiven, and in a great measure forgotten, they leave very disagreeable feelings among all parties.

## DUTIES OF MASTERS AND SERVANTS.

From the earliest ages down to the present time there have been different classes of society. As elsewhere explained, this necessarily arises from the very order of society. The well-established and very proper right of inheritance, and the ability which some members of society have to acquire, and which others have not, the difference of education, and other obvious causes, necessarily produce these distinctions. Who among the various classes is the most contented and

happy is quite another matter. There must be some to serve, and some to be served. They are mutually dependent. We hear great complaints, sometimes from masters with regard to their servants, and sometimes from servants with regard to their masters or employers. This connection is regarded as one of the miseries of life; yet it is not necessarily so. If the connection produce vexation, there must be error somewhere. We shall first speak of the duties of masters:—

It is the duty of masters to cultivate the esteem and affection of those whom circumstances have placed under them. Servants have the same sort of bones, muscles, heads, and hearts, the same self-love, and the same sensibilities, as their employers. They may not be so refined, still they have rights to be maintained, and must not be tyrannised over merely because they are in an inferior condition. They have as good a right to be happy as those above them. If they behave with propriety, and do their duty, they should be spared when sick, advised and relieved when in trouble, and be made as comfortable as circumstances will permit. The commands given to them should be plain, clear, uniform, and not contradictory or capricious. They are not to be sneered at, or commanded with virulence and reproach, but mildly, and rather by request. They are also to be treated with uniform civility and kindness; but every approach to familiarity with them should be avoided, if respect on both sides is to be preserved. It is always best to let servants know what is their duty, and what is expected of them. Much mischief is sometimes created by not attending to this rule.

The duties of servants to masters are equally clear. Their entering into servitude is a contract which they engage to fulfil. They are bound to execute all reasonable and proper orders in the line of service in which they are engaged. But besides this, they would consult their interests in being generally obliging and willing to assist in any kind of exigency. A seeming wish to please an employer goes a great way to compensate for deficiencies in ability. A civil, obliging turn, is indeed one of the chief virtues in a servant, and is certain to secure the affection of masters and mistresses. A strict attention to an employer's interest, regularity of habits, and perfect integrity both in speech and action, form the principal qualifications of a servant. There is usually much less actual dishonesty among servants than a regardlessness of their masters' interests and time. This is more the case with domestic than other servants. This class of persons, who are chiefly females, are very apt to encroach on the time of their employers for their own pleasure and convenience. If sent an errand, they will spend a great deal of more time in executing it than is necessary. It is an idle love of gossiping which generally produces this great failing among servants, and it is our duty here to admonish them of its impropriety. Their time belongs to their master, and it is dishonest to use it for their own purposes, unless by permission. Speaking with regard to persons in service generally, we are sorry to notice that there is a tendency to reduce the terms of contract betwixt employers and employed to one of a purely mercenary nature—so much work for so much money. There appears to be a growing inclination to drop all kindness of intercourse betwixt the two classes. The consequence is, that many masters feel perfectly indifferent with respect to giving employment to those who have long served them. The injury is, however, mutual; for when servants know that they are only valued in proportion to the amount of their actual labour, and that they will be paid off without regret, they care little for a master's interest. There can be no question as to who began this improper system. It originated in servants and workmen endeavouring to establish by violence and intimidation a certain amount of wages for their labour, and which the state of society could not warrant. We earnestly trust that it is not yet too late to restore the ancient bond of sympathy betwixt every description of employers and employed. Individual and social benefit would be the result.

## DUTY OF TRUSTING TO OURSELVES.

There is a duty of an important nature which we have to perform towards society; and that is, we must *trust to ourselves*. We have each been endowed with reason to guide us, and hands to work; why, then, unless prostrated with bodily disease, or some other infirmity, should we think of leaning upon others for support or assistance? It would not be desirable to see men shut up their hearts against each other, and each stand in the panoply of his own resolutions, determined against every friendly appeal whatsoever. It is possible, however, to be not altogether a churl, and yet to take care lest we be tempted into an exertion of benevolence dangerous to ourselves, while it is of little advantage to our friends. Notwithstanding the many ties which connect a man with society, he nevertheless bears largely imprinted on his forehead the original doom, that he must chiefly be dependent on his own labour for subsistence. It is found by all men of experience that in so far as one trusts to his own exertions solely, he will be apt to flourish; and in so far as he leans and depends upon others, he will be the reverse. But there are many who do not recognise this principle. They trust only partially to themselves, and are always poking about after large favours from friends. We find them asking loans of money, asking others to be surety for them, asking acquaintances to interfere to get places for them. If they ask for nothing else, they intrude upon their friends to seek advice. Neither physically nor morally do they seem able to exert themselves for their own behoof. This is so contemptible a mode of living, that it cannot be too severely reprehended. Those who depend on others can never succeed in life. In whatever manner they may be assisted, they can never become front-rank men in society. We would earnestly impress upon the young the propriety of depending as little as possible upon prospects of advantages from others, all of whom have enough to do with themselves. It is obviously the duty of every one to think and act for himself as soon as he attains manhood, and neither be burdensome on relatives nor troublesome to acquaintances. The acceptance of a trifling favour from an acquaintance always lays us under an obligation, which is sometimes difficult to remove. If the acquaintance ever need similar favours, we feel bound to grant them; and perhaps he estimates the original favour so highly, that he thinks we cannot do enough to serve him. In this way hundreds of men are ruined. We would say, as a general maxim, accept no favours, unless upon a principle of common courtesy. If you employ others to execute a piece of work, take care to pay them faithfully and promptly, and lie under no obligation to them, otherwise you may be called upon, when you least expect it, to make payment a hundredfold. Be liberal, affable, and kind; but, knowing that you cannot do more injury to society than by greatly injuring yourself, exercise a just caution in giving way to the solicitations of your friends. Never be too ready to convince yourself that it is right to involve yourself largely, in order to help any person into a particular station in society; rather let him begin at the bottom, and he will be all the better fitted for his place when he reaches it, by having fought his way up through the lower stages.

## MAKING A WILL.

Much distress among families is often produced by individuals who have property to bequeath, not making a will or testament. Why such individuals do not make their wills it is difficult to explain. Perhaps it arises from carelessness and a spirit of procrastination, or a want of resolution in men to make up their minds with respect to how they would distribute their property at their decease. Some may indeed be so foolish as to imagine that the making of their will would hasten the approach of death. From whatever cause it proceeds, it is a highly blameable failing. It is the duty of every person possessing property, whether engaged in busi-

ness or otherwise, to make a will, and describe in some species of document how he would wish his affairs to be arranged in the event of his dying. There certainly are cases in which men of property would not wish their possessions to be distributed in any other way than as the law would dictate; yet it is a mark of a well-regulated mind to leave a will descriptive of the means to be pursued in the accession to, and management of, their property and concerns. To do so at least would often save a great deal of trouble and some expense, and be a preventive of litigation among relations. We therefore must insist that the making of a will is a sacred duty which ought to be performed, and performed without procrastination. In the midst of life we are in death; no one knows but in an hour hence he may be no more. We beseech fathers of families, and others similarly placed—those even who may have property but to the value of a few pounds—to lose no time in executing their will. By leaving so much as a letter subscribed by their name, to be opened after their decease, they may spare much vexation to those whom they hold dear; they may quench much petty jealousy, much unseemly disputation and strife.

#### MISFORTUNES—EVILS.

Evil is a part of the system of things in which we live, and, as such, must be patiently submitted to. Man was intended to be an active creature. One of the grand aims of the Creator in his formation evidently was, that he should never settle down into a sluggish or stagnant state. It would have been easy for the Divine power which breathed into him so wonderful a thing as life, to have surrounded him with nothing but blessings, as they are called, so that he would have nothing to do but enjoy himself. But this would not have produced what the Almighty wished—a world in which a rational being was to exercise his faculties, and use his endowments, with a proper regard to a certain end; an account—namely, to be rendered at the close—of what and how he had done. We are here placed between evils which we are to avoid or subdue, and good which we are to aim at and enjoy; and hence, instead of being a set of torpid machines, as we would have been in anything like a world of perfect happiness, we are in a perpetual state of vigilance and activity, making the fullest use of those mental and bodily properties with which we have been gifted.

If we narrowly inspect the evils or misfortunes with which we are visited, we will find them invariably to be either of two kinds. Some are the simple result of an occasional and habitual violation of the laws of nature, or an occasional or habitual failure in that vigilance and activity which we are bound to employ for the avoiding of such distresses. These may be called moral evils. The second class are the result of circumstances over which we had no control, and may therefore be called natural evils. Such a division, however, is only necessary in the present state of our attainments as a race; for there can be no doubt that means were intended to be discovered by the ingenuity of man for the avoidance and neutralisation of all evils whatever; and therefore, in the case of what we call natural evils, we should only consider ourselves as the victims of imperfect knowledge, and be on that account, the more induced to strain after the improvement of ourselves and of our fellow-creatures, so as to obviate these as well as the rest.

Great care should be taken, when an evil befalls us, to ascertain whether it be moral or natural—in other words, whether it be the consequence of our own error, or of circumstances at present beyond our control. Our self-love makes us extremely apt to attribute all our mishaps to the latter cause; but if we are wise, we will not do so. We will rather search back unscrupulously into our own nature, or our own history, for the causes of the evil; and if we find them there, resolve for the future to be more circumspect or more active, so as to make a recurrence of the mischief less likely. The most of the accidents that occur, though they appear

at first sight to be natural evils, would be found, on close inspection, to be moral. The most of the diseases that befall us could be traced to a failure in our duty to ourselves, and are therefore moral evils: the rest, such as cancers, wens, organic malformations, &c., which appear natural and unavoidable, are, we have no doubt, moral evils also. If *we knew better*, we might probably avoid them, as easily as we can avoid colds. They may be called natural in the meantime, but not so unless mankind strive to discover their causes, so as in the long-run to obviate them. They are certainly destined to be obviated at last, as many disorders, now understood, formerly were; and men must at present consider them only in the light of an inducement to the exertion of the spirit of inquiry.

There are some evils which we incur through hereditary channels, and are quite beyond our own control. We are charged, for instance, with the seeds of a harassing ailment, or of an early death, by the long foregone and perhaps long-repent-ed vices of our parents. But all this may be accounted for on the same principle. It has been intended that our moral natures should be so much improved, that even the possible distresses of a descendant may operate as a check to our wickedness; and what is a contemporary instance of innocent consumption, but a warrant to prevent us from doing that which may bring future lives into the same hazard? It is hard in the meantime for the sufferer; but what can we say against the course of nature? Perhaps the spectacle (and few can be more painful) of a youth dying in his very bloom, in consequence of natural debility derived from weakly parents, may be the means of preventing two persons from putting themselves into the situation for bringing on similar evils. A very high kind of conscientiousness, but one not unattainable even by ordinary minds, is called into force by the contemplation of such a case of unbought distress. A man who has any reason to fear for the validity of his own constitution, will, if fully impressed with a sense of such results, as likely to arise from his quitting a condition of celibacy, condemn himself to perpetual solitude rather than purchase an improvement of his own happiness at the expense of unreckonable evil to others. Fortunately society is beginning to look more narrowly into such matters than it used to do; and we do not despair of seeing a time when it will be nearly as infamous to communicate life under certain circumstances, as, under others, to take it away.

There are other evils which affect society, and which do their full part in making this a world of wo. There is squalid miserable poverty; there is disgusting lamentable vice; there is horrible crime, public execution, and national war. All these things, it is said, are inevitable; they spring from the nature of man, and from the laws which compel him to dwell in social connection. Those who say so are shallow thinkers. The world is naturally a beautiful world. But what God has made a paradise for our dwelling-place, mankind have often rendered a desert by their crimes. Nature and revelation alike proclaim that the Creator intended we should be happy; but how has brutal ignorance, vile intemperance, gross crime, and every species of evil desires, blighted our comforts and degraded our immortal being! It has never yet been proved that there must necessarily be poverty, which is the source of many evils. A striking instance of the absence of poverty in a large class of society is found in the case of the Quakers, or community of Friends. With some peculiarities in speech and dress, not worth while to heed, this numerous body of individuals act upon a fixed uniform principle of suppressing the passions. They curb the appetites and headlong impulses of human nature. In this may be said to lie the substance of sound morals. The Quakers, therefore, habitually practise what other classes only theorise upon, at least are seldom performing. The consequence of this guardedness in thought and action is, that although there are many thousands of Quakers in Great Britain, and many thousands in the United States of America,

neither in the one country nor the other do we ever find a Quaker begging in the streets, or an intoxicated Quaker, or any one of this class of subjects and citizens at the bar of a criminal court! The Quakers are, like other people, engaged in the common affairs of the world; they are merchants, mechanics, artificers, mariners, and otherwise employed in the ordinary business of life. They are subject to the same temptations and perversions that we are; yet, by the exercise of a singular degree of self-respect and prudence, they avoid them. Here, then, is a clear demonstration, that even without the aid of civil power, but by the mere force of moral influence, there is a class of men in the midst of society who do escape disgraceful poverty, and who are free from outrageous vice and crime.

With regard to death, which is so generally looked upon as an evil, and the last and worst of all, it is in reality no such thing, unless it occur prematurely, which it never would do if men were perfect in the observation of the laws of nature. As the conclusion of an existence which never could have been given if others had not died, it must be regarded as only a part of our earthly destiny, and submitted to accordingly.

#### INEQUALITY OF RANK AND CONDITION.

When the young grow up, they find society to consist of classes of various degrees of rank and condition; some with titles of distinction, others without any title whatever; some rich, some poor, and many in a middle state between great wealth and poverty. The youthful reasoner perhaps thinks that all this is wrong, and that by *natural right* all men ought to be upon a level. It is proper that not only the young, but others who take up notions of this kind, should be told why these differences originate, and why they exist. Mankind, we may suppose, were originally equal in rank and condition; and they might have remained so, or nearly so, had they continued to remain in primeval barbarity, and lived apart from each other. But it was not in their nature to remain in this condition. According to naturalists, man is a gregarious animal—that is, he desires to live in society. As soon as men began to consort together, they began to separate into ranks and conditions. He who was the bravest was made king; he who was the most clever or the most prudent became the most wealthy; he who was the most idle became the most poor. From this kind of beginning all ranks and conditions sprung; and subsequent events have modified society into what we now see it. It may be said that this explanation would do very well if we now found that those who enjoy distinctions in rank were the cleverest of the people; if we found that the richest were always the most deserving of riches. Here again we must apply to human nature.

In one sense titles are contemptible; they are fantastic trappings which a wise man would not covet. But, on the whole, there are few men possessing that degree of wisdom and self-denial which would lead them to despise titles or the dignities connected with them, when applied to themselves. As far as we can discover, the Quakers are the only people who do not regard these things. The citizens of the United States of America affect to despise titles; yet it is curious they give a title of distinction to their chief magistrate, whom they style '*His Excellency*;' they also write *Master*, or its contraction *Mr*, before their names. In this we see a degree of the same vanity and weakness which affects the subjects of ancient monarchies. It would appear that there is a yearning after these follies among mankind. Be it so or not, it is an idiosyncrasy which, from time immemorial, has been seized hold of by rulers for the purpose of stimulating men to deeds beneficial to their country. The prospect of being entitled to write *Sir* before their names, or of being called a *Lord*, induces numbers of individuals to do great and good actions, which they would not do for money. As these titles generally descend to their children, they have a double stimulant to action. Genius not being hereditary, these titles may and do fall into the possession of

men of no ability; nevertheless, the stimulant to acquire titles such as they have, continues to act beneficially, as it is thought, through the nation; and they themselves feel bound to sustain a certain honourable character consistent with their rank. And although that equality of rank for which visionaries contend is utterly unattainable in any state of society, yet in this happy country there is a more important kind of equality which is enjoyed by every individual member of the community: all British subjects are on a footing of perfect equality in the eye of the law. In our courts of justice no difference is recognised between the peer and the peasant. The highest rank cannot protect the offender from the vengeance of the laws; the most obscure condition will not prevent the aggrieved party from having the strictest justice administered to him. And besides, there is no rank or condition to which a British subject may not successfully aspire; the proudest honours of the peerage, and the highest offices of the state, being open to the ambition of all who possess sufficient merit to entitle them to such distinction.

The principles of human nature apply in a similar manner in solving the mystery, why there are men enjoying riches which they never wrought for, and may be undeserving of. Riches consist of that part of the surface of the earth which can be used for human habitations and their appendages; of that part which can be used to produce vegetation; of that part over which, and near which, there are flowing waters capable of imparting motion; they consist of all personal estate; and of money, the agreed representative of all property, which is, at the same time, property in itself. Possessions of these various kinds are acquired by inheritance or by industry. Right by inheritance is not wrong. Would any rational mind maintain that, when the father of a family, or any one who has no family, has acquired property, and dies, that it shall belong of right to any and to all who can get possession by fraud, force, or whatsoever other means they may? Society could not be held together if such were the rule of right. It is at once apparent that if such were the rule, there would be nothing to contend for, because all inducement to acquire for the benefit of one's family and connections would be annihilated. Society would be forthwith reduced to barbarism. The right to acquire, and the right of inheritance, are wisely ordained to be a necessary consequence of society, and one of its strongest motives to act to useful ends.

If it be irreconcilable to justice, to convenience, and to the common good, to take by fraud or violence that which the dead must have left behind them, much more so is it to take from the living, by like means, that which they can honestly acquire by the exercise of their own industry. If a member of a community were always liable to be despoiled of the fruits of his labour, the great principle of the system of being to which man belongs would have been misplaced: there would have been no sufficient motive to action. If one would know what society would be, if such were the law and the practice as to property inherited or acquired, he must visit countries steeped in barbarism, and on which the light of Christianity does not shine.

It is contended by some persons that there should be a periodical division of land and property, and that every member of the community shall have an equal share. How often should this division be made? Shall it be made once a year, once in ten years, once in fifty years? Why should it be made at one time rather than at another? Suppose it could be made, and were made, it must be but a very short time before it ought to be made again, if the reason for making it be, that some have more and some less, and that some are rich and some poor. One must be wilfully blind not to see that either the whole action of society must stop, or that inequality of condition would arise in a single year, perhaps in a single month; and even such inequality as would call for a new division. In a country where the spirit of enterprise and speculation has an unrestrained agency, the causes of regret are, that sad

reverses occur, and that property changes hands too often, rather than that it is unreasonably held in the hands of a few of their successors. A small number of generations is sure to bring equality, considering our community as a continuing one. Thus property comes and goes, in this and other free countries, as fast as any one can reasonably desire to have it. The changes which are seen as to the ownership of it are regulated by authority far wiser than any of man's institution.

## ON FORMING OPINIONS.

Opinion signifies belief. There are good and bad opinions. It is our duty as rational beings to cultivate good or correct opinions upon every subject, and to eschew those which are of a contrary description. There is nothing more easy than to form hasty, inaccurate opinions, but it is very difficult to form a correct belief on many topics. Opinion is found to be more or less dependent on times, circumstances, and bodily temperaments. It frequently arises out of prejudice, and is often influenced by impulse. When we form an opinion upon any subject, we are inclined to believe that all opinions of an opposite character have been, and are, erroneous. We are apt to laugh at everybody's opinion but our own. All this betrays a deficiency of sober reflection, an ignorance of the history and faculties of mankind, and a want of knowledge of the world. The people of every country possess opinions favourable to their own fashions, customs, laws, and religion, and unfavourable to those of other nations. A love of one's own country is certainly a commendable feeling, but it should be a love arising from examination and conviction, not from prejudice. The Hindoo worships the river Ganges. *We*, by our education, know that this is nonsense. The bigoted but conscientious Turk will go to death upon it, that Mohammed was a true prophet. *We*, by our superior intelligence and reading, know that Mohammed was a vile impostor. The people who lived in our own country a hundred years ago were of belief that certain old women, whom they termed witches, could, by supernatural powers, raise tempests at sea and land, and malevolently interrupt the course of human affairs. The people who possessed this belief were perfectly conscientious in their opinion; yet we know that this opinion was a gross absurdity. *We* know that our ancestors believed in an impossibility. Opinion is therefore, as we see, a thing of time and place. The opinion that is supposed to be right in one century, is wrong in the next. What is considered to be a right opinion in Asia, is thought wrong in Europe. What is deemed a correct and praiseworthy belief in Britain, is reckoned an absurdity in France. Indeed it is often seen that the opinion which is held good in one district of a country, is looked upon with contempt in other districts—so that the whole world is found to be covered, as it were, with a variety of opinions and shades of opinions, like the diversified colours by which countries are depicted in a map. Opinion, we have said, is also dependent on temperament of the body. This is a melancholy truth. A fat and choleric man does not think in exactly the same way as a lean man. A man who enjoys all the comforts which opulence can purchase, has a tendency to think differently in some things from a man who is suffering under misfortunes or poverty. So strangely constituted is the principle which governs human opinion, that most men have reason to alter their opinions on many points in their progress through life.

What does all this wonderful contrariety of opinion teach us? Since we see that opinion is dependent on the locality of our birth, on the age in which we live, on the condition in which we may chance to be placed, and on the physical qualities of our bodies, have we therefore no power over opinion? Must we be its slave? These are questions of a solemn character, and we must answer them soberly. The contrariety of opinion existing in times and places teaches us, in the first place, *humility*, which is the foundation of many heavenly virtues. It shows us that the opinions which

we may form, particularly on abstract subjects, may possibly neither be the most correct nor the most enduring. Perhaps what we have taken up and cherished as our opinion may after all be a delusion. In learning a lesson of humility and distrust of our own style of thinking, we are impressed with a tender regard for the opinions of others—opinions which most likely have been taken up on grounds equally conscientious with our own.

Although opinion is commonly dependent on those contingent circumstances which we have noticed, it cannot be allowed that we have no power over it. We have a power over the formation of opinion to a certain extent, and it is our present object to show how this power can be exerted in order to enable us the better to fulfil the duties of life. The reason why opinion is so illusory in its nature is, that mankind have ever been excessively careless in the adoption of their opinions. They are in the habit of picking up random ideas, which they mould into an opinion; and after having made up their minds, as they call it, on what *they think* is their opinion, they will listen to no explanation of the opinions of others. Their obstinacy, their self-conceit, their self-interest, their wish to please the party to which they have attached themselves, induce them to hold fast to their original opinion, until time or experience in all likelihood wear it down, and its absurdity is secretly pressed upon their notice. But even after its absurdity is disclosed, they are sometimes ashamed to say they have altered it; and so perhaps they have one opinion which they keep locked up in their bosom, and another which they bring into daily use, and flourish before company. In the opposite language of Scripture, these men war against the TAVRN.

It is our duty, as good members of society, and with a view to self-respect, to be very cautious in the formation, and, most of all, in the display of our opinions. Many excellent men, on arriving at middle life, have deeply regretted that they should have heedlessly published their early and hastily-formed opinions in youth. They had reasoned, as they thought, soundly, but it was without a knowledge of the world or its history. Speaking to the young, we would say—while yet under the training of parents, guardians, and teachers, it is your duty to receive with confidence the instructions by which it is attempted to enlighten your minds, and to put you in the way of well-doing. But these friends of your youth will probably tell you that when you pass from under their guardianship into the active scenes of life, you become a responsible being—responsible alike to human and Divine laws—and that you must now think for yourself. At this critical period of your existence you have every chance of coming in contact with the idle, the dissipated, the frivolous, who will try to make you embrace erroneous opinions, and who will possibly put the most mischievous books into your hands for perusal. Do not be led away by such machinations; neither be dismayed by the number of wits or profane jesters who may assail you. Do your duty manfully. In order that you may attain a correct opinion on the great debateable subjects that you will hear rung in your ears through life, begin a course of reading those good and authoritative works which intelligent friends will recommend to your notice. Take every opportunity of cultivating your understanding, of enlarging your ideas, of banishing prejudices. Look always at the different sides of a question; for you must remember that there are always many ways of telling a story. In proportion as you advance in your private studies, and acquire a knowledge of the passions and conduct of mankind, you will more and more be able to form a correct opinion. There is one thing which you will learn with surprise from this kind of experience; and that is, that many, though holding different opinions, are driving towards the same end in the main. They have only differed upon trifles, and perhaps fought about mere words. This is one of the strange weaknesses of the human race, into which you will find it difficult to avoid falling. The more that you learn, the

more will you see cause to entertain a liberal view of the opinions of others. It is the exercise of this liberality of mind which forms a distinguishing trait in the manners of our country. By the British constitution, every one is allowed perfect freedom of opinion, a gift above all price, which it is our duty not to prostitute or abuse. Let us form our opinions on solid grounds of conviction—let us cherish these opinions to the adornment of our lives—and let us so maintain a due regard for the opinions of others, that we show forth in our feelings and actions that most excellent and amiable of all virtues—CHARITY.

These observations apply indifferently to various subjects upon which opinions may be formed; and we would, in conclusion, beg to say a few words in particular on opinions of a political nature, which are the most difficult of all to be correctly formed. Political opinions are applied to the theory and practice of national government. The policy of national government is not an exact science to be learned, as some would imagine. It is more a fashion than a science. It is a thing dependent on time, place, and other circumstances. The form of government which suits one age or country would not suit another age and country. Some nations are best governed by a despotism, others by a mixture of monarchy and democracy, others by a pure republicanism; but, as we say, what is best at one time is not best at another. The genius and necessities of every people are subject to change, and consequently their governments change with them. If we feel the force of these facts, we will be cautious how we assume an unalterable opinion upon any mode of administering government. The young are particularly liable to take up notions on this subject which they afterwards feel inclined to fall from. We would admonish them to read and digest the history of their country, and reflect well upon the genius of the nation, before they come to a determinate opinion in politics. They will learn, as they advance to maturity, that in nothing is there such a mass of duplicity and affectation as in political matters. They are therefore called upon by duty to examine extensively, and probe deeply, the grounds upon which they form their opinion. They will find it much the safest course, as already expressed, to think lightly in the matter till they have had some experience of the world, and been convinced by the evidence of their senses. National exigencies sometimes call upon us to engage more deeply in politics at one time than another. Discretion must here be our guide; yet there is generally greater danger in our wasting much precious time on political disquisition, than in falling into an apathy upon public affairs. He is a wise man who knows how so to guide his steps as to preserve himself from falling into either extreme. Every one who has been for a long series of years politically busy, will acknowledge, that though he thinks he was right in the main (in which opinion he may be right or wrong), yet that he has spent many busy hours and anxious thoughts on subjects which, looked back upon, are seen to have been profitless and insignificant.

#### DUTIES WHICH THE PEOPLE OF ONE COUNTRY OWE TO THOSE OF ANOTHER.

It is seen that all the people of the earth belong to some one of the many nations with which it is covered. It is also seen that nations are generally separated from each other not only by language, manners, customs, religion, and forms of civil government, but also by geographical boundaries. The division of mankind into nations is natural, and possesses obvious advantages. There is a limit beyond which the government of a nation cannot well be administered. By being confined within certain limited bounds, the national institutions may be improved, security and prosperity promoted, and the interests of the people advanced. We frequently find that the people of one nation live at enmity with those of another nation. We find many at open war with their neighbours—that is, they are resorting to brutal physical force to settle a dispute. These are

evils deeply to be deplored. Nations have mutual wants, which a mutual intercourse and trade will obviate. They have similar interests at stake. Their inhabitants all alike belong to the great human family, and should live at peace with each other. But ambition, and many evil passions—strife, malice, and uncharitableness—are continually in operation to retard their advancement towards a universal philanthropy. National war is the heaviest curse which afflicts humanity. It leads to enormous debts and taxations, and in reality is the beginning of all kinds of distresses among the people. Yet the people have been frequently very clamorous for war. We say *have been*, for we hope that this sentiment will in future be otherwise regulated. We ought to impress upon our minds a surpassing horror of war. Let us think of it as the scourge of the human race, and as one more destructive, physically and morally, than the most virulent epidemic. Were the inhabitants of countries duly impressed with these feelings, did they reflect upon the blessings which are showered upon nations during a lasting peace, they would henceforth resolve to oppose, by every constitutional means, the commencement of wars by their governments. Besides the actual loss of lives and of property to a nation during war, it is incalculable the injury sustained by society by such an infliction. A war of a few years' duration may retard intellectual improvement for a century. We hold, therefore, that it is the duty of every man to discountenance such a system of folly. He cannot be a lover of his country, he cannot be the friend of moral cultivation, who would countenance such an idiotic process of settling quarrels between intelligent nations. According to a rational view of men's condition in separate nations, war can in no case be reconcilable with social happiness, unless on the obvious principle of self-defence. So long as there remain such masses of ignorance over the earth, so long, we are afraid, force must be employed to preserve the little spots of civilisation from the flood of barbarism which might overrun them. May it be anticipated, however, that this urgent necessity will not exist much longer! How glorious would be the prospect if universal peace were permanently established! We should find one nation instructing another in all the arts and sciences of which it was itself master: we should find an honourable spirit of emulation running through the whole; and all shaping their policy so as to promote the most beneficial intercourse in commerce, literature, and refinements. In the present state of things, as far as it can be accomplished, a kind and friendly international communion is a high moral duty. It is our duty to look with an eye of charity on national peculiarities. We have no right to insult the feelings of the people of any nation, however strange their language, their fashions, or their customs may appear to us. We have likewise no right to taunt them with any apparently improper characteristics in their forms of government. It is our duty to consider them as entitled to live and act according to their own fancy, as independent responsible beings. To write, print, and disseminate any scurrilous jests tending to lower them in general estimation, is not only immoral, but inconsistent with those principles of manly honour which do not permit any one to be struck who cannot defend himself. When we therefore insult a foreign nation by our obloquy, we commit the mean and cowardly action of injuring a party which has no means of redressing the grievance.

#### RECREATIONS AND AMUSEMENTS.

We have often had occasion to show that this state of being is one of alternate action and repose. There must be serious action, and there must be amusements. It was intended that mortals should be pleased and happy, if they deserve to be so. Those who maintain that life is to be an uninterrupted scene of labour and gravity are, we hope and believe, entirely mistaken. We discern nothing in the natural world, nor in man's peculiar constitution or relations, which gives the least

countenance to such an opinion. Amusement, like everything else in which free agency is concerned, may be innocent and grateful, or improper, pernicious, and introductory of the worst of evils. Young persons must have the former, or they will seek out the latter. It is the duty and the interest of parents to lead children to take pleasure in such things as can be approved of, and to divert children from such as must be injurious to them, and afflictive to those who are deeply interested in them. We apprehend that there may be persons, and classes of persons, who will disagree with us on this subject, as they may have done on some which have been already touched upon. We should deeply regret to displease any one; but on a matter so important as the making good citizens and moral agents out of children, one should not hesitate to speak frankly. If wrong, persons better able to judge will take care that no evil visits them in consequence of such error.

Amusements are physical or mental. It may be more proper to say that there may be, *first*, amusements which are intellectual, and *second*, such as consist of some bodily motion, in which the mind is more or less interested. If there be such distinctions, athletic sports may be of the second sort. The simple use of the eye, of the ear, and of the imagination, may be of the first sort. It is believed that all amusements must have some contemplated end or result, whether that be defined and certain, or contingent. We believe so, because everything in this world seems to be moving on to some purpose. One who is acting without knowing for what, is neither labouring nor amusing himself, but is trying to get rid of himself, and of time. The most captivating sports are those which are contingent; that is, sports or occupations wherein the result may be highly favourable or otherwise. No one engages in them without expecting to come out on the successful side. Hence hunting, fishing, horse-racing, and gaming are of this order. The hope of success is a very high excitement, but the mortification and distress of failure ever far exceed the pleasures of success. There is a tendency to discourage out-of-door sports. This is certainly wrong. If not carried to excess, they are among the most salutary and pleasing amusements in fine weather.

Every one admits that the mind and moral faculties are to be developed, and strengthened, and made to do the best, by exercise. This is equally true of physical power. Every action which it can be proper to do at all, ought to be done in the best way, otherwise we do not answer the end of our being. In the vegetable and animal departments, all proper care and cultivation tend to use and beauty. Is there any reason why the physical powers of man should not have care and cultivation to the same end? Those who prefer a stooping, lounging, awkward, graceless figure and motion, may be on one side of the question; those who think that it was intended that man should be an upright, easy, frank, comely, and convenient being to himself, and pleasant to all within whose observation he may come, will be on the other.

Although the frame of man is so made as to permit him to assume an endless variety of positions, and to apply his strength in all of them, he does, or should, return always to an upright position. No essential deviation from this position can possibly be a natural one, but for a temporary purpose. This is proved by the framing of the human bones. This framing shows that when one walks, it was intended that he should be perpendicular; if he walk in an inclined position, he has not only to move himself, but to resist the power of gravitation at the same time. The muscles in such case have a strained and unnatural duty to perform. It seems to have been intended, by the same sort of proof, that human beings should walk with the lower limbs—that is, from the hips downward—and not with an unmeaning and ungraceful action of the whole person, as is often seen to be done.

*Dancing.*—As to the best modes of acquiring strength, ease, and grace, there may be very different opinions. There are many who think the discipline of *danc-*

*ing* a proper mode, and others who think this highly improper. We would not run against any opinions, whether well or ill-founded. But as to dancing, just like everything else, it may be misused and perverted, or be made to be an innocent, healthy, and commendable accomplishment. There is no mode so much within the reach of the community in general as this. Properly taught, it brings out the power of the muscles, and gives them their natural action: all natural motion is graceful. Why should not man conform to this general law of nature? Dancing well is one mode of conforming. Possibly it is considered frivolous and corrupting. Nothing is frivolous in this system of being which is innocent, pleasing, and adapted to promote healthy action. Persons who are capable of being corrupted by dancing, will certainly find some much more effective mode to become so if this be denied to them. Dancing among the very young is usually conducted under the eye of discreet seniors, and well-educated adults need no supervision in dancing but that of good sense and their own self-respect. But suppose dancing could in any case be perverted, so may everything else be. If we are not to do anything till it is impossible to err in doing it, what will there be for any one to do?

*Music.*—It is one of the most convincing proofs of the benevolence of Deity, that he has so formed the human ear as to make it capable of finding a rational and elevated pleasure from the action of sound. There might have been organs of speech, and ears to hear, without imparting to the ear the power of knowing and delighting in music. It must have been intended that this gift should be used, and (most probably) as one mode of praise and thanksgiving, as well as for innocent pleasure. Music is action; it is action to some end; the end is innocent and delightful. The enjoyment has the advantage of being solitary and social. Music may be made to produce a sense of high moral feeling, and it may be made to produce feelings of an opposite character. The same rules must be applied to this subject as to all others, that everything was created, and for some good and wise purpose; and that everything must act, and will act, to some useful end if human ignorance or error do not interfere.

It is consistent that man, as he is so superior to all other animals, should be alike superior in the making and enjoying of musical sounds. He undoubtedly is so. His voice (it would be more proper to say woman's voice) includes all the sweet sounds which can be made by all other animals. He has, by cultivating this power, by applying the atmosphere through the human lungs, and by delicacy of touch, and by bringing substances in contact with each other, and by sending the wind through that wonderful work of his own hands, the organ, found the means of rendering tribute to the Most High, and of softening and purifying his own heart. No doubt music was given to mortals for their amusement, and it is their duty to take it in that light, and be thankful for it.

*Games.*—Games at cards are a very common amusement. They may be innocent, but there is nothing to recommend them. They give no action to the body; they are a very humble occupation for an intelligent mind. Whether the chances in distributing fifty-two pieces of spotted pasteboard fifty successive times in three or four hours shall possess some of the engaged with fortunate pieces, and others with unfortunate ones, can hardly be said to be doing anything to any useful end. When the sport is over, the thing proved or arrived at is, that in this use of four hours of a short life, A counted so much, and B so much. This, however, is not the end usually proposed in playing cards. The cards are only the machinery which, with more or less skill, submits to the laws of chance the result of emptying one man's pocket and filling another's. A passion for this kind of gaming extinguishes, or converts into a withering curse, every fine feeling of the human heart. Time, health, property, the proper use of the tongue, character, self-respect, and peace of mind, are the sacrifices made at the gaming-table. Unnoticed by the miserable victim,

the shackles of habit are put on, which no earthly power can unrivet. When the gambler's last shilling is gone, he starts as from a dream into a full sense of the complicated misery and ruin in which he has involved himself. He must then devote himself to infamy, and submit himself to the power of a gravitation which will bring him inevitably to the bottom of its abyss. The evils of gaming may be readily judged of by the number of suicidal deaths which it occasions, especially in the great cities of Europe.

All gaming for property leads, in proportion to its character, to such results. The means of gaming, and especially with cards (as they are the easy and most common implements in use), are regarded with the abhorrence which is associated with them by all persons who feel an interest in the young. The young and the middle-aged have no need of cards for amusement. They may have many amusing occupations which are innocent and improving. There may be persons in an advanced time of life, who are beyond the seduction of gaming, to whom the interest of a game of cards may be an innocent and welcome amusement. Undoubtedly, friends who are met for social purposes, and who have nothing better to do with their time, hands, and minds, may play cards in a manner to give no offence to themselves or others. But it is pleasing to know that the state of improvement is such, that in most social meetings there are higher entertainments than that which cards afford, and which are justly in higher esteem.

There might be games, one would think, adapted to amuse children, and to be at the same time innocent and useful ones. Whatever they are, they must be consistent with the principle which requires a beginning, an interesting succession of circumstances, and a result worth attaining. Children must be busy. To require of them to be still, is to require what nature has forbidden. To place a child on a hard bench, and tell him to sit still there two or three hours, without any employment for his hands or mind, is as great a violation of natural law as to require of him to stand on his head for the same length of time. There is an obvious want in the means of amusing children; and we apprehend that it arises from disregarding the principles on which the construction of physical and intellectual being rests. If there were an extensive workshop, provided with every variety of tools, with a proper superintendent, to which boys might resort on some proper arrangement, and where they could make articles for themselves, there can be little doubt that it would be diligently frequented. The reason is, that their little efforts would be to some end, and by natural means. On the other hand, the gymnastic machinery is fallen into disrepute. These exercises are uninteresting repetitions to no end, except with those who know that bodily motion must be had to secure health. In such cases they endure the labour for the end in view. But the amusements of the young must be of a nature to secure action to an innocent and useful end, and health will take care of itself. Perhaps there may be some persons who can follow out this matter, and invent rational amusements. They would deserve to be regarded as benefactors, and would probably find a substantial reward. We cannot but remark that there is one game which is one of the most interesting and healthful that can be played—that of tennis or handball. There are many things to recommend it; and among others, it is one sufficiently interesting to be played for itself, without adding to it the zest of winning or losing anything but the game. We incline to think that it is the game, of all others, which deserves the patronage of colleges and seminaries, and is well adapted to develop the physical force.

*Conversation.*—The principal amusement of rational people is the interchange of thoughts by speech or conversation, which word is made out of the Latin words *con* and *versor*, and means literally *to be turned to or with*. The principal of this amusement is found in the law of association of thought. Intelligent persons can always make a conversation. The only difficult step is the

first; that ought not to be so considered. Persons who are skilled in the art of talking can always give it a direction. The purposes of conversation are, to put one's self in the way of learning something; to impart something that others want to hear; to form opinions on interesting subjects; to settle the merits or demerits of public action; to recount amusing or extraordinary facts, &c. &c. Every human being knows something which he is willing to tell, and which any other that he is in company with wishes to know; or which, if known to him, would be amusing or useful. To be a skilful conversationalist, one's eyes and ears should be busy; nothing should escape his observation. His memory should be a good one, and he should have a good-natured willingness to please and to be pleased. It follows that all matter of offence in conversation should be avoided. The self-love of others is to be respected. Therefore no one is tolerated who makes himself the subject of his own commendation, nor who disregards the feelings of those whom he addresses. There is as much demand for politeness and civility in conversation as in any other department of social intercourse. One who rudely interrupts another, does much the same thing as though he should, when walking with another, impertinently thrust himself before his companion, and stop his progress. Under favourable circumstances, and among persons who know how to train a conversation, there are few, if any, amusements more grateful to the human mind. We need not say anything of the amusement derived from reading. It is very properly one of the standard amusements of persons of all ages. The influence of the press on the character of a country is not to be measured or calculated. It is strikingly true of this admirable invention, as it is of so many other things in natural and moral agency, that, *well used*, it is an inestimable blessing; ill used, the corrupting demon of social life. Happily, attention to the proper wants of the young has required of the press its action for their benefit; not as to books of severer study only, but sheets of amusement.

#### RELIGIOUS OBLIGATIONS.

Religion signifies a system of faith and worship. Religion arises from man's perception of his relation to the system of being of which he is a necessary part. The presence and influence of religion is to be felt and manifested throughout the duration of human life, in all that is thought and done, with a view to a happier and more perfect state of existence after death. Just conceptions of the character and attributes of the Deity are of the utmost importance, especially to the young, whose minds require to be led aright in all that pertains to the great truths of religion. The religion professed in this country is Christianity—the most cheering, the most noble of all faiths. The books to which we point for instruction in the religion of Christ are those of the Old and New Testament. To them the instructors of the young will direct the religious studies of those under their charge as may best seem fit. Besides inculcating religious obligations, these works furnish us with the most perfect system of moral duty ever promulgated. The sum of the earliest delivered moral law is comprehended in the Ten Commandments, which are as follows:—1. Thou shalt have no other gods before me.—2. Thou shalt not make unto thee any graven image, or any likeness of anything that is in heaven above, or that is in the earth beneath, or that is in the water under the earth: Thou shalt not bow down thyself to them, nor serve them: for I the Lord thy God am a jealous God, visiting the iniquity of the fathers upon the children unto the third and fourth generation of them that hate me, and showing mercy unto thousands of them that love me, and keep my commandments.—3. Thou shalt not take the name of the Lord thy God in vain; for the Lord will not hold him guiltless that taketh his name in vain.—4. Remember the Sabbath-day, to keep it holy. Six days shalt thou labour, and do all thy work: But the seventh day is the Sabbath of the Lord thy God; in it thou shalt not

do any work, thou, nor thy son, nor thy daughter, thy man-servant, nor thy maid-servant, nor thy cattle, nor thy stranger that is within thy gates: For in six days the LORD made heaven and earth, the sea, and all that in them is, and rested the seventh day: wherefore the LORD blessed the Sabbath-day, and hallowed it.—[By the practice of Christians, the Sabbath has been transferred to the first day of the week.]—5. Honour thy father and thy mother, that thy days may be long upon the land which the LORD thy God giveth thee.—6. Thou shalt not kill.—7. Thou shalt not commit adultery.—8. Thou shalt not steal.—9. Thou shalt not bear false witness against thy neighbour.—10. Thou shalt not covet thy neighbour's house, thou shalt not covet thy neighbour's wife, nor his man-servant, nor his maid-servant, nor his ox, nor his ass, nor anything that is thy neighbour's.

Such was the sum of the moral law until Christ added to it a number of the most transcendently excellent admonitions, and which are found scattered throughout the history of his ministrations in the four Gospels in the New Testament. The chief moral which he inculcated was, 'Whatever ye would that men should do unto you, even so do unto them; for this is the law and the prophets.' But the whole of his sayings breathe a similar spirit of benevolence and gentleness. He preached, for the first time that it had been done on earth, the doctrine of 'peace and good-will towards men;' that is, universal love and peace among all mankind. 'Ye have heard,' said he, 'that it hath been said, Thou shalt love thy neighbour, and hate thine enemy: but I say unto you, love your enemies: bless them that curse you: do good to them that hate you: and pray for them which despitefully use you and persecute you.' Again, he said, 'Blessed are the poor in spirit, for theirs is the kingdom of heaven: blessed are they that mourn, for they shall be comforted: blessed are the meek, for they shall inherit the earth: blessed are they which do hunger and thirst after righteousness, for they shall be filled: blessed are the merciful, for they shall obtain mercy: blessed are the pure in heart, for they shall see God: blessed are the peacemakers, for they shall be called the children of God: blessed are they which are persecuted for righteousness' sake, for theirs is the kingdom of heaven: blessed are ye when men shall revile you, and persecute you, and shall say all manner of evil against you falsely, for my sake.' In this manner he taught the great necessity for being humble and lowly in spirit, as the basis of all virtue and social happiness. He likewise inculcated at different times the necessity of putting away everything like ostentation in doing good actions. He tells us not to give our alms before men, but to bestow them in secret; not to pray ostentatiously in public, but in a private place. No one until he appeared ever pointed out that there was no difference betwixt actual transgression and the wish to transgress. He tells us that sins of the heart are equally punishable with the commission of an offence. He likewise taught that men 'cannot serve two masters;' that is, do evil actions, however apparently trivial, and at the same time be good men. To break 'the least of the commandments' is to be reckoned equivalent to breaking the whole; and it is further said, it is impossible that our obligations to God can be accepted of so long as we live at enmity with a brother; that is, having a quarrel with any one. 'Leave thine offering before the altar, and go thy way; first be reconciled to thy brother, and then come and offer thy gift. Agree with thine adversary quickly whilst thou art in the way with him.' Who amongst us, may we ask, keeps this saying in remembrance? Do even all who attend the public worship of God most strictly and punctually hold it in mind!

Again, he says that we are equally to avoid hypocrisy, or a pretence of self-righteousness and ability to show our neighbours their faults, before we have put away the same or other faults from ourselves. 'Hypocrite, first cast the beam out of thine own eye, and then thou shalt see clearly to cast out the mote out of

thy brother's eye. Judge not, that ye be not judged.' How valuable are these reproofs! Continuing to admonish us of the danger of hypocrisy, he says that we shall know men by their fruits; that is, we shall know them by their actions, not their words. 'A good tree cannot bring forth evil fruit, neither can a corrupt tree bring forth good fruit: therefore by their fruits ye shall know them. Not every one that sayeth unto me, Lord, Lord, shall enter into the kingdom of heaven; but he that doeth the will of my Father which is in heaven.' We are likewise told that there must be no stop to the extent of our forgiving of injuries. Being asked if we should forgive an injury for seven times, he said to those about him, 'I say not unto thee, until seven times, but until seventy times seven;' by which we are to understand that there is to be no limit to our forgiveness. Three things, we are told by St Paul, are essential—Faith, Hope, and Charity, but that the greatest of these is Charity, or a disposition to think well of our neighbours whatever may be their actions. It is also variously inculcated that charity is the first of the Christian virtues. Personifying it, it is said, 'Charity suffereth long, and is kind; charity envieth not; charity vaunteth not itself, is not puffed up, doth not behave itself unseemly, seeketh not her own, is not easily provoked, thinketh no evil; rejoiceth not in iniquity, but rejoiceth in the truth; beareth all things, believeth all things, hopeth all things, endureth all things.'

CONCLUSION.

We have now given an elucidation of what we consider to be the principal duties we are called on to perform during life, both to ourselves and to others. The subject is by no means exhausted, yet enough has been said to afford human beings a view of what line they ought to follow in the pursuit of individual and social happiness. The object we held in view has been accomplished. We have, to the best of our ability, put young and old, high and low, rich and poor, in the way of executing their temporal duties. We hope we have shown that if a man be not a happy, a grateful, a satisfied being, he must accuse himself, and not complain that the system of being to which he belongs is wrong and malevolent. We have attempted to prove that man, individually and socially, is capable of improvement; that he has removed himself from his original condition, and has advanced far in disclosing his own powers, and in applying them to the promotion of his own happiness. But it has to be added, that he has still much farther to go in the same course, that the way is known to him, and that there are no obstacles in it which he may not remove. We do not believe in the perfectibility of mankind. The crimes and follies which affect even the most cultivated of our race tell us too plainly that there is a natural bias towards evil, which it requires the utmost skill on the part of religion and reason to counteract. The passions ever seem to stand as a barrier against human perfection, and it is only by their due regulation that we can gain so much as comparative worldly happiness. Yet it is incalculable to what extent the exaltation of the mental faculties may be carried by education, and to what extent the community may be purified of its vices. Let us hope that nothing may occur to interrupt that physical, intellectual, and moral improvement of society which is now so happily in the way of advancement.

NOTE.—The preceding article was an abstract from the Moral Class-Book of Mr William Sullivan, a work published at Boston in the United States. The present is partly original, and partly selected from the same production. Excellent as Mr Sullivan's book is, it is singularly deficient in the inculcation of some of the principal public duties, and is in many parts adapted only for the perusal of American readers. The heads in the present abridgement.—Duties of Subjects, as Electors, as Jurors, as Masters and Servants, Conduct at Public Meetings, Making a Will, Misfortunes and Evils, Inequality of Rank, Duties which the People of one Country owe to those of Another, Duty of Trusting to Ourselves, Religious Obligations, and Conclusion, are original.

# POLITICAL ECONOMY.

## DEFINITIONS.

POLITICAL ECONOMY is the science which teaches the manner in which nations and individuals acquire wealth.

*Wealth* is anything which is capable of gratifying our desires, and of procuring for us by exchange some other object of gratification. Some objects are capable of gratifying our desires, but are incapable of procuring for us any other objects in exchange: such are air, the light of the sun, and commonly water. Others are capable not only of gratifying our desires, but of procuring for us other objects in exchange: such are fuel, cloth, salt, wheat, iron, money, &c. It is only articles of this latter class that are denominated wealth.

*Value*.—That quality in any object which renders it capable of gratifying our desires is called its *value*. Thus the value of air consists in its power to support life; the value of water consists in its capacity to slake our thirst, and in its utility in the several purposes in the arts; the value of fuel consists in its capacity to impart to us warmth, to cook our food, &c.

When this value is considered simply as a capacity to gratify human desire, it is called *intrinsic value*.

When it is considered as a capacity to procure for us something else in exchange, political economists term it *exchangeable value*.

Things which are everywhere abundant, and which require no aid from human labour to render them capable of gratifying our desires, have only intrinsic value. This is the case with air, the light of the sun, &c.

On the other hand, things which derive their power to gratify our desires from human labour, and which are found only in particular places, have always exchangeable value. This is the case with articles of food, clothing, metals, minerals, &c.

The reason why these latter have exchangeable value is evident. If I, by my labour, give value to something which had no value before, I have a right to the thing in which this value resides. And inasmuch as I have bestowed my labour upon it, I will not part with it for nothing. Hence if any one wants it, he must offer me in exchange something on which *he* has bestowed a similar amount of labour, or else something which I could not otherwise procure without bestowing upon it an equal or a greater amount of labour. Thus if I have spent an hour in catching a fish, I will not give it to my neighbour for nothing, or for air, or sunlight, which I can have for nothing. I will only give it for something which I could not procure with less than an hour's labour. And if he offer me something which I could procure with half an hour's labour, I shall not exchange, but shall prefer to procure for myself the article which he offers me.

And hence we see that when men exchange the products which they have procured with each other, they exchange labour for labour. Thus when men exchange silver for gold, they give a much larger amount of silver than of gold, because it requires much more labour to procure gold than it does to procure silver. Again, they give a much larger amount of iron in exchange than of silver, because the labour of procuring silver is much greater than the labour of procuring iron.

And hence we see that when men exchange with each other, the exchangeable value of anything will be, in general, as the labour which it costs to procure it. Hence the *cost* of anything, or its *natural price*, is the labour which is necessary to produce it.

This, however, is liable to accidental and temporary fluctuation. Sometimes a much larger quantity of a given product is created than is wanted. In this case the owner, in order to induce persons to buy, will offer it at a less price than the cost, because he had rather

sell it at a loss than lose it altogether. When in this case the supply is too abundant, the exchangeable value will fall. On the other hand, when not enough of any given product has been created to supply the wants of the community, the buyers, rather than be deprived of it, will overbid each other, and thus will pay more than the natural price: that is, when the demand is unusually great, the exchangeable value will rise. These causes of fluctuation can, however, exist but for short periods; and the constant tendency of the exchangeable value of any ordinary product will be towards the cost of the labour necessary to create it.

*Production* is the act by which we give to any object its particular value, or its particular capacity to gratify human desire. Man can neither create nor annihilate anything; he can only change the form of that which is created. We cannot create iron, but we can extract it from the ore; we can then convert it into steel; we can change a bar of steel into knife-blades. Each of these acts, by which a particular value is given to the iron, is called an act of production.

The substance to which any value has thus been imparted is termed a *product*.

*Capital*.—The term capital is applied to the material before it has been changed by labour into a product; to the instruments with which this change is effected; to the means of subsistence by which the labourer is supported; and also to the product which results from the application of labour to the raw material.

*Exchange*.—Every man finds it for his interest to labour exclusively at one kind of production. Thus we see that every man has his own trade or profession. But a man wants a great many other things besides those which he produces himself. The shoemaker produces shoes; but he cannot eat, or drink, or clothe himself with shoes. Hence he must exchange his shoes for those articles which he needs. Every other man is in the condition of the shoemaker. And hence we see that an immense amount of exchanges must be made every day in every civilised community.

*Distribution*.—Not only does every man work at a particular trade—it is commonly the case that a great many men must labour together in order to create a particular product. Every penknife, nay, every pin, goes through the hands of several workmen, and receives a portion of its value from every one of them. When the product has been created, every one is entitled to his share of it. The principles by which this division of the profits is made, is called by political economists *distribution*.

*Consumption*.—Every product, after it has been created, is put to some purpose. Sometimes it is used for the creation of some other product—as wheat, when it has been raised, is used for the purpose of making flour; or again, it may be used for the simple purpose of satisfying human desire—as bread, when it is eaten, is used to appease our hunger. The destruction of values in this manner is called *consumption*.

The whole subject of Political Economy may therefore be comprehended under these four divisions—Production, Exchange, Distribution, and Consumption.

## I. PRODUCTION.

*Production* has already been defined as the act by which we confer upon any object a value which it did not possess before; or it is the application of *labour* to *capital* for the creation of a product.

### CAPITAL.

*Capital* is the material which is to be united with industry for the creation of a product, or the *instru-*

ments which are used in the act of production, or the *necessaries and conveniences* by which the health of the labourer is sustained. Sometimes the labourer finds the material in its native state, as the miner finds the ore or the coal in its native bed; most commonly, however, he receives it from another individual, who has already conferred upon it some value, and it is his occupation to confer upon it additional worth.

The forms of capital are as various as the different occupations of men. The *material* of the farmer is seed, manure, animals, &c.; that of the manufacturer, cotton, wool, iron, leather, &c.; and that of the merchant, the various substances in which he traffics.

The *instruments* with which these producers labour are very various. The farmer uses ploughs, harrows, and carts; the manufacturer, saws, hammers, and spinning and weaving machines; and the merchant, ships, boats, locomotives, and the like.

Besides these, all men require for their *sustenance* food, clothing, shelter, and the various conveniences of life. Viewed in this light, all capital may be included under one or the other of the following classes:—

*Changes of Capital.*—Inasmuch as the labour of men is so universally employed in changing capital having one form of value to capital having another form of value, capital must be incessantly undergoing change. It is no matter how many changes it undergoes, if its value be at every stage sufficiently increased to pay for the labour which it cost to effect the change.

*Increase of Capital.*—If a given material undergo a change by which its value is increased, then there is an increase of capital equal to the *difference* between its former and its present value. I say equal to the *difference*; because, in the creation of one value, another value is always destroyed, and we are benefited, therefore, only by the superior amount of value which we possess over that which we have consumed to produce it. Thus the farmer consumes seed, manure, labour, sustenance, in the production of a crop. He has changed one kind of capital for another, and he is enriched just by as much as his crop is of greater value than all that it cost him to produce it.

Capital which is undergoing change by which its value is increased, or which is yielding an annual income, is called *productive capital*. That which is lying idle, and neither producing anything nor increasing in value, is called *unproductive capital*.

*Money* forms a small, but very important part of the capital of all civilized nations. The use of money is to enable us the more easily to make exchanges with each other. That it forms but a small part of the capital of a country is evident from the fact, that a very small part of the wealth of any individual consists of money. What is true of the separate individuals of a community must be true of the community collectively.

*Fixed and Circulating Capital.*—That capital from which the owner derives profit by changing its form or place, is called *circulating capital*; while the various instruments which he uses to produce this change, and from the use of which he derives profit, are *fixed capital*. Thus the wheat and the manures of the farmer, the wool and raw cotton of the manufacturer, are their *circulating capital*; the ploughs, harrows, barn, and land of the one, the machinery and buildings of the other, are their respective *fixed capitals*.

There is a constant tendency in a prosperous condition of society to change circulating into fixed capital. The farmer sells his wheat, and with the produce buys more land and better tools, or erects better fences and barns. The manufacturer, with his profits of this year, enlarges his manufactory; and thus, in the progress of society, vast sums are annually invested in roads, canals, manufactories, and various means of improvement.

The beneficial result of this tendency is easily seen. Fixed capital is but slowly consumed, hence the wealth of each generation is transmitted to the next; and, year after year, a country becomes better and better provided with the means for furnishing itself with all the conveniences of life. The superior conveniences

which we enjoy in this country over those enjoyed by the aborigines who long ago occupied it, are owing entirely to the amount of fixed capital which covers the soil. It is thus that the results of the industry of men are transmitted to their posterity, and that the men of any one age are enabled to reap advantage from the skill, industry, and good conduct of the men of all ages who have gone before them.

## INDUSTRY.

Of the Nature and the different Kinds of Human Industry.

*Industry* is human exertion of any kind employed for the creation of value.

If we consider the different kinds of value which it is in the power of man to create, we shall see that human industry may be employed in three different ways. Matter may be changed in its *elementary form*, as it is by the farmer when he plants seed and reaps an increase; or in its *aggregate form*, as when a carpenter fashions a piece of furniture out of a log; or in its *place*, as when a sailor carries it from one country to another. The ultimate design of all human industry employed in production is to effect either one or the other of these results. They are frequently, for the sake of distinction, denominated *agricultural, manufacturing, and commercial industry*.

It is evident that every one of these kinds of labour is absolutely necessary, in order to promote the convenience and happiness of man; and also that neither one could prosper without the aid of the others. Were there no *agricultural labour*, everybody would starve. Were there no *manufacturing labour*, everybody would be chilled to death. Were there no *labour employed in transporting commodities from place to place*, no one could enjoy any convenience except what he had produced himself—that is, though with great industry and suffering a few persons might live, yet they would be but few, and these few would be miserably poor. Hence we may see how unwise it is for any jealousy to exist between the farmer, the mechanic, and the merchant. All are equally necessary to each one, and each one is necessary to both the others.

But some men are neither mechanics, nor farmers, nor merchants; they are students, or philosophers, or lawyers, or physicians, or clergymen. All of these men, however, are necessary to society in ways that must be generally obvious, and are as well entitled to their rewards as any other useful class.

Of the Increase of the Productiveness of Human Industry by the means of Natural Agents.

By the productiveness of human industry we mean the amount of product which a human being in a given time can create. Thus if a farmer by one day's labour can raise one bushel of wheat, the productiveness of his labour is equal to one bushel; if he can, with the same labour, raise two bushels, the productiveness of his labour is equal to two bushels. If a cotton-spinner can spin one pound of cotton in a day, this is the amount of the productiveness of his labour; if he can spin ten pounds, this is the amount of it.

Now it is evident that the greater the productiveness of labour, the better it is for the industrious person and for all his neighbours. Every one knows that it is better for a farmer to own rich than to own poor land, because with a year's labour on the one he can obtain a much larger crop than on the other. It is, moreover, better for him that his neighbours also should have rich than poor land, because the richer their land, the larger quantity of *their products* will they be able to give him in exchange for *his products*. The great difference, therefore, between rich and poor land is, that rich land renders industry *more productive* than poor land.

The case is the same with the other modes of industry. He who spins with his fingers without any machine labours very unproductively—that is, in a day he can create but a small product: he who labours with a

spinning-wheel, labours much more productively—that is, with a day's labour he can create a much larger amount of product; and he who uses a still better machine, called a spinning-jenny, labours yet more productively—that is, in a day he can create twenty or a hundred times as much product as he could with a spinning-wheel. In every case, as the productiveness of labour increases, both the labourer and the community are benefited, just as a farmer would be benefited by exchanging a poor soil for a rich one. In both cases the benefit is the same—that is, with a given amount of labour he creates a larger amount of product, he receives better wages for his labour, and at the same time the community obtains his product at a cheaper rate. Hence it is that mankind have been, from the earliest ages, endeavouring to invent means by which the productiveness of human labour may be increased. And the condition of mankind is improved, from time to time, just in proportion as these endeavours have been made successfully. Every one knows how much the comforts of an industrious mechanic in this country exceed those of an uncivilised Indian; and the difference is owing to the fact, that the labour of the one is *so much more productive* than that of the other.

Now there are two ways in which the productiveness of human industry may be increased: these are, first, the *use of natural agents*; and, secondly, *division of labour*. Let us explain:—

**Use of Natural Agents.**

A *natural agent* is, as its name imports, an agent of nature, or any quality of things which we are able to use in order to accomplish our purposes. Thus it is of the nature of wood, when set on fire, to give off heat, and heat is the natural agent which we use for the purpose of cooking our food. It is of the nature of steam, when heated, to expand, and when suddenly cooled, to contract; hence steam is the natural agent by whose alternate expansion and contraction we create the force which we need to propel boats or machinery. So it is of the nature of water, when falling down from an elevation, to acquire a very considerable force; this force is the natural agent which we use to turn the wheel of a mill. So the peculiar quality of the magnet is a natural agent. The various qualities of medicinal herbs are also natural agents, though used for a different purpose from those mentioned above.

A *tool* or a *machine* is any instrument by which we are enabled to avail ourselves of the qualities of natural agents. Thus an axe is an instrument by means of which we make use of the cutting power of iron. A steam-engine is an instrument by which we make use of the expansive and contractile quality of steam.

In political economy, the principal use of natural agents is either to create or to use power or force, or, as we sometimes call it, momentum. Thus if a man wishes to row a boat, or chop wood with an axe, he must have strength or power with which to do it. The more strength or power he has, the more work he can do. Thus a man can do more work than a boy because he has more strength, or power, or force, to do it with. Now natural agents are capable of exerting this power, and by means of machinery we can direct the manner in which it shall be exerted.

The natural agents which we use for this purpose are of two kinds, animate and inanimate:—

Animate natural agents are beasts of burthen and draught—as the ox, the horse, the ass, the camel, the elephant, and other animals similarly employed.

That these very greatly increase the productiveness of human labour is evident. Every one knows how much more land a farmer can cultivate by means of a pair of horses than he could by his own unassisted strength, and how much more wheat a man can transport from one place to another with a wagon and horse than he could carry on his back.

The inanimate natural agents are, as we have said, the various qualities and powers of things by which we are enabled to accomplish our purposes. The most im-

portant and familiar of these are gunpowder, wind, falling water, and steam.

*Gunpowder* is used in war, in hunting, and in the blasting of rocks. For the latter purpose it is very valuable in the construction of canals, railways, &c.

*Wind* is used as a stationary agent in the common windmill; and as a locomotive agent in the propelling of vessels on the water. It is cheap, and for some purposes very valuable.

*Falling water* is used very extensively as a stationary agent in almost all works where great power is required. Almost all our nails are made, our wheat is ground, and much of our cotton is spun and woven by water.

*Steam*, however, is now used the most extensively for the various purposes of the arts, as it possesses many advantages over every other agent. It is capable of exerting any degree of force, from the least to the greatest; it may be used as a stationary or a locomotive power; it may be used on land or on water, and it may be placed perfectly under human control. Its only disadvantage is its expensiveness. Steam is now used to spin the finest thread and the stoutest cable, to weave muslins and to hammer anchors, to propel the largest vessels on our rivers and on the ocean, to draw our carriages, to saw and plane our boards, and in fact to accomplish almost all the purposes which require either great or unremitted force (See No. 25, Vol. 1.).

Inanimate agents are in general preferable to animate agents in most of the purposes for which power is required. The reason of this will be readily comprehended. For instance—

1. *They are cheaper.* A steam-engine of a hundred horse-power will cost less than the horses necessary to do the labour which it performs, and will cost much less to keep it at work.

2. *They labour without cessation*, while animals require much time for rest and refreshment.

3. *They are safer.* They have no passions, and hence may be governed by fixed and certain laws. A steam locomotive, for example, is neither liable to run away nor be frightened.

4. *We can use them without the infliction of pain*, while animals frequently, of necessity, suffer in consequence of hard labour or rapid driving.

5. They are capable of much more rapid action, hence there is a great economy of human time.

But this is not all. Men are able not only by the above means to create force, they are also able to devise machines by which the force thus created may be applied. Thus after a steam-boiler and cylinder have been constructed, we are able to create a force by means of steam; but we still need levers, and wheels, and cranks, in order to enable us to use it. When we have trained horses to draw, we still need wagons to enable them to draw with. All these machines, by which force is directed, are the various modifications of what are called in philosophy the mechanical powers. And by means of them we are enabled to wield the force which we have created in any manner that we choose.

Besides these agents for the creation of force, there are various other qualities of things which are of very great use in the purposes of human life. Thus, for instance, some of the metals, when heated, readily melt; and if in this state they are poured into a mould, they retain the shape of the mould with perfect precision. In this manner much human labour is saved, or a given amount of labour is rendered much more productive. Were it not for this quality of type-metal, every type must be cut by the hand. This would render types and books very expensive. But now we have only to cut a mould into the form that we wish, and if the melted metal be poured into it, the type is formed, by cooling, into the precisely corresponding figure. In this manner a single workman can make several hundred types in an hour. There are various other qualities of things which we use in a similar manner, but their number is so great that we have no room here to describe them. By reflection, every person may easily furnish himself with as many examples as he pleases.

In the preceding sections we have seen that the productiveness of human labour may be greatly increased, *first*, by discovering the various qualities of things, or, specially, those qualities by which we are capable of creating force; and, *secondly*, by those various contrivances by which the force thus created may be successfully directed and applied. We have one other source of increased productiveness yet to consider—it is division of labour—and its results are in many cases as striking as any that have been noticed.

Division of labour, in general, means employing one individual upon one kind of labour, instead of employing the same individual upon several kinds of labour. If we reflect, we shall see that this circumstance forms one of the leading distinctions between savage and civilised nations. A savage does for himself whatever he requires to have done. He is his own philosopher, inventor, and operative; his own farmer, butcher, baker, shoemaker, tailor, carpenter, &c. And the result is, that he is ignorant, hungry, shelterless, almost naked; and that he continues age after age without making any sensible improvement. On the contrary, civilised men divide these various occupations, so that one man labours wholly in one, and another man labours wholly in another employment; and the result is, that civilised men, without labouring more than savages, easily obtain convenient shelter, clothing, food, and all the necessaries of life.

But still more. Every one who observes any mechanical process, observes that it consists of several parts. For instance, in order to make a knife, the blade must be formed and then polished, the handle must be formed in several pieces, the rivets must be made to connect these several pieces together; and after these several pieces have been formed and prepared for each other, they must be united together into a knife. Now what is commonly called division of labour in political economy, consists in so apportioning this work that one person shall labour at only one part of any process.

The division of labour in this manner is found to have a much greater effect upon the productiveness of human industry than could possibly have been supposed. Every man who labours at a trade adopts this plan in part. If a cabinet-maker, for example, have a dozen tables to make, he will make all the legs of all the tables at once, then all the covers, &c. and when all have been prepared, he will put them all together. And if several men were to unite and make nothing but tables, and each one perform but one part of the labour, they could make a great many more tables in a given time than if each one made a whole table.

The principal reasons for this increased productiveness are as follow:—

1. It saves the loss of time and skill, which must result from frequently passing from one occupation to another. After a man has laboured for some time at one thing, he is said to have 'got his hand in,' and he performs the operation with ease and skill. If he turns to a different occupation, his 'hand is out,' and he cannot perform it so well. Hence all the time consumed in acquiring the habit is lost.

2. When a variety of operations is to be performed by the same individual, he must frequently adjust his tools, or pass from the use of one kind of tools to the use of another. This occasions a great waste of time. By performing the same operation continuously, the same tools with the same adjustment will answer the same purpose perpetually. This is specially the case where the adjustment of tools requires not only time but expense, as, for instance, in the use of the blacksmith's furnace. If the smith heat it, and leave it for the purpose of doing some other work, all the fuel consumed after he leaves it, as well as that necessary to bring it again to its proper temperature, is lost.

3. When men confine themselves to a single operation, they acquire a degree of dexterity and skill which could be acquired in no other manner. A man who

only occasionally makes nails, may make about 800 or 1000 in a day; while a boy who has never done anything else, will make upwards of 2300 in a day.

4. Division of labour suggests the invention of tools and machines, by which labour may be rendered still more productive. As soon as an operation is analysed into its simple processes, it is comparatively easy to contrive some way in which to perform either one or all of these processes by a machine. It would have required great skill to construct a machine for making nails before the process was analysed; but let it be divided into rolling, cutting, and heading, and it is comparatively easy to construct instruments by which each of these processes may be accomplished.

5. There is great diversity in the talent required for performing the various parts of a process. Some parts of the operation require great dexterity, and a long course of education; others can be performed by women, and even by children, with very little training. Some parts may require labour worth four or five shillings, while others can be executed by labour worth no more than a few pence per day. Now without division of labour, all the processes must be performed by labour at the highest price. By judicious division of labour, the manufacturer can employ just the amount and just the kind of labour that he needs. This greatly reduces the cost of production.

The effect of all this is seen in the very low price at which almost all the articles of general use may be obtained. For instance, suppose a lady in New York wanted a dozen needles, and applied to a jeweller or other workman to have them made for her, she could not obtain them at much less than a shilling a piece. But needles are imported into that city from a British manufacturing town, and sold at about four for a half-penny of our money, notwithstanding all the cost of transportation; and this entirely through the advantage derived from the division of labour.

1. But to this division of labour there is a natural limit. This limit depends upon several circumstances. For instance, a given process consists of no more than a certain number of operations. When it has been divided into as many parts as there are distinct processes, and one part is assigned to each individual, this is as far as division of labour can go. There would be no economy in any farther division.

2. Again, the practicability of division of labour depends upon the capital of an individual or of a country. A man must have accumulated some considerable amount of capital before he can carry on division of labour in any occupation. For instance, suppose that the division requires the labour of ten men, he must have materials and tools sufficient to employ ten hands. Nor is this all: suppose that it take ten days to finish his product, he must have material sufficient to employ them during all this time before he receives anything in return for that product. And if it take a fortnight more before he is able to sell his goods and obtain a fresh stock of material, he must have a capital sufficient to employ them during this time also. It is for this reason that manufactures do not commence with the first settlement of a country, but they must always be delayed until capital accumulates before they can be successfully established.

3. Division of labour can only be carried on where there is sufficient demand for a product to consume it as fast as it is manufactured. If it would take *ten* men to manufacture pins by division of labour, but only so many pins could be sold as could be made by *one* man, the labour could not be divided. This, however, depends upon several other circumstances. For instance, the demand depends upon the number and the wealth of a community. There is a larger demand for hats in a town of ten thousand inhabitants than in a village of one hundred inhabitants. There is also a greater demand for hats among a thousand rich men than among a thousand beggars. This is another reason why division of labour and manufactures naturally increase with the growth, and age, and wealth of any country.

And hence we see why roads, canals, and railways are so beneficial to the industry of a country. By reducing the cost of transportation, they render the price of any commodity as low at one hundred miles distance as it frequently was before at ten miles distance from the place of its manufacture. Hence facility of transport increases the number of consumers, and by thus increasing the demand, renders practicable the division of labour in cases where before it was impracticable.

Again, it is evident that demand must be greatly affected by the cost of the article manufactured. Costly articles are purchased only by the rich. But the rich are only a small part of the community. Hence the demand for such articles is but small. It is those articles which every one wants, and which every one can buy, that create such a demand as will enable them to be made at the cheapest possible rate. Hence we see that division of labour, and the reduction of price which it occasions, benefits the poor much more than it does the rich. I do not suppose that jewellery, trinkets, rich laces, are much, if at all, cheaper than they were twenty or thirty years ago; while cotton cloth, hardware, woollen goods, and all the manufactured necessaries of life, have fallen in price from one-half to three-fourths. This is an immense benefit to those of us who are obliged to spend our money for necessaries and comforts, and have none to spend for trinkets.

#### Of the Benefits of Increased Productiveness of Labour.

The prime object of labour, as every one knows, is to procure the means of happiness. A farmer labours to produce wheat, rye, fruits, &c.; a cotton manufacturer to produce clothing, and a shoemaker to produce shoes, and so of any other case.

Now the greater the productiveness of labour, the greater are the means of happiness which the individual by a given amount of labour produces. If a farmer expend a year's labour upon a rich soil, his labour is more productive than if he expended it upon a poor soil; that is, with the same labour, he produces in one case say five hundred bushels of wheat, and in the other case only two hundred bushels. Every one must see that this is an advantage; and every one would rather own one hundred acres of good soil than one hundred acres of poor soil.

Now if a poor soil can, by means of manure, or in any other manner, be changed into a fertile one, the result is the same as if, by means of improved tools, a farmer were able by one day's labour to produce twice as much as he could produce before.

Now this principle applies just as much to a manufacturer or any other labourer as to a farmer. Suppose a carpenter, when he first commences learning his trade, could not make more than one table in a week, his labour would be very unproductive. As he becomes more and more skilful, he can make a table in less time; and at last, when he can make a table in a day, his labour is six times as productive as it was before, and he has the means of procuring for himself six times as many comforts with the same amount of labour. Further, if he be able, by means of a turning-lathe, or a steam-engine, or by division of labour, to make two tables a day, his labour will be still more productive, and he will be able to procure for himself a corresponding greater amount of conveniences.

So if men spun by hand and wove by hand, were this possible, a man could produce but very little thread and very little cloth. His labour would be in the lowest degree unproductive. But if he invent a spinning-wheel and a loom, his labour becomes at once vastly more valuable, and he can produce ten or twenty times as much as he could before, and he is able to provide himself with a much greater portion of the necessaries and comforts of life. If now we furnish him with a spinning-jenny and a power-loom, his labour will be still more productive; and as he creates, with a given amount of labour, a greater amount of the means of happiness, a larger portion will fall to his own share—that is, he will be both richer and happier. And facts demon-

strate that such has always been the result. The labour of the Western Indian or the Eastern Hindoo is without machinery and without division, and it is of course very unproductive. Hence he is very poor. The whole wealth of the Indian is a blanket and a bow and arrows, and the whole wealth of a Hindoo is a pot of rice and a cotton cloth. How different is the condition of the labourer in this country!

And we also see that it is not beneficial merely for one individual to increase the productiveness of his labour; it is beneficial to the whole community that the sum-total of industry should be as productive as possible. Would it not be a benefit if the crops of corn, and wheat, and cotton, and rice, the products of the fisheries, of the mines, and of the manufactories, during the next year, should with the same labour be doubled, so that we might by a day's labour procure twice as much bread-stuff, fuel, clothing, and every necessary and comfort of life, as we are able to procure at present? Now the whole effect of the increased productiveness of labour, by means of machinery and of division of labour, is to bring about precisely such a result.

And yet more—the benefit of this change is specially realised by the labouring-classes. A nobleman in Great Britain is by no means as much better off than his ancestor, as a common labourer in England now is better off than a serf at the period of the feudal oppression and ignorance. The rich and powerful in all countries always have an abundance of comforts and luxuries. Comparatively, they are but slightly benefited by improvement in the productiveness of labour. It is the labourer who is chiefly benefited, because every improvement brings within his power some convenience which was before out of his reach. What difference does it make to a man worth a hundred thousand a year whether coal costs one or five pounds a ton, and cotton cloth fourpence or two shillings a yard? At either price he would be able to procure an abundance. But to the man who is worth but fifty or a hundred pounds a year, the difference of price is a matter of immense consequence; inasmuch as at one price he would be able to supply himself abundantly, and at the other price he would be able to supply himself but very scantily, if he were able, indeed, to supply himself at all. Hence we affirm that improvements in machinery, by which the productiveness of labour is increased, are specially for the benefit of those classes who are obliged to work for their living.

The only objection to all this is, that by increasing the productiveness of labour we diminish the demand for labour, and that hence labourers are thrown out of employment. This deserves a brief consideration, inasmuch as it has led not only to erroneous views in theory, but to practical wickedness in action.

To settle this question, let us examine the facts. What are the manufactures which now employ the greatest number of workmen, and in which the number of workmen has within the last twenty years the most rapidly increased? I think that any one will answer, the cotton and the iron manufactures. But if we were asked in which branches of manufactures has labour-saving machinery been most extensively introduced? we must also answer, the cotton and the iron manufactures. Or we may come to the same result if we compare the linen with the cotton manufacture. Machinery has been introduced only in a small degree into the manufacture of the one, and very extensively introduced into that of the other. The consequence is, that the labourers in linen are very poorly paid, and are diminishing in number, while the labourers in cotton are well paid, and are every year rapidly increasing. These facts are abundantly sufficient to teach any person what is the natural result of the use of machinery.

The reason of this is easily seen. Suppose that only 10,000 yards of cotton could be used in a given district, and it required 100 men to make them. If these 10,000 yards could be made by 50 men, it is evident that 50 men would be thrown out of work. But suppose that by this change in the mode of labour, the cotton cloth

which was sold at 2s. could be sold at 1s., so that *twice the quantity* could be used, and 20,000 yards were wanted, there would be a demand for just the same number of workmen as before, so that the workman would be just as well off as he was before. But suppose that when cotton was at 2s. a yard, only those worth £200 a year could afford to purchase it, while now that it is at 1s., those worth only £100 per annum can become purchasers. The number of persons in a community worth £100 a year is more than double that of those worth £200. Hence this class alone would create a demand which would place the labourer in as good circumstances as he was before. But to this must be added the demand of those worth £120, £150, and £200; and it must be remembered that each one of these classes will now use more cotton cloth than the class of £200 did formerly. To this must also be added the fact, that by the reduction of price, cotton cloth may be used for many purposes to which it could not formerly have been applied. All these circumstances taken into the account, will show us how it is that the greater the productiveness of industry, the greater will be the wages of labour; and that the more extensively labour-saving machinery is introduced into any department, the greater will be the demand for labourers.

But this is not all. While the labourer is thus benefited in his wages by the use of machinery, he, and every other person, is equally benefited in another respect. We have seen that by this means every product is rendered cheaper. Every one knows how much cheaper woollen and cotton goods, carpets, books, and most of the necessaries of life are than they were a few years since. Not only are they cheaper, they are also better and more elegant. Calicoes, crockery, the various fabrics for wearing apparel, paper-hangings, and many other things, may be procured at a very reasonable price, and of great beauty of appearance. These benefits the labourer shares with the rest of the community. Hence his share of the advantage is doubled. His wages are raised, and the price of what he purchases with them is reduced. The rich man receives no higher interest for his money than before—that is, his wages remain the same: his only advantage is, that with the same money he can procure what he wants at a cheaper rate, or in greater abundance.

OF THE CONDITIONS OF SOCIETY FAVOURABLE TO PRODUCTIVENESS.

It is essential to the promotion of industry that a man should enjoy the reward of his labour. Every man must be allowed to labour as diligently as he can, and to use as he pleases all that he has gained, provided that he use it innocently.

For these purposes it is necessary that all the property in a community be divided. By this it is meant that everything belongs exclusively to some one. In the first place, the land must belong to particular persons, otherwise it will not be tilled at all. We see this principle strikingly illustrated in the condition of a country inhabited by savages, and also in the state of most *commons*, wherever these exist. No one having any particular interest in the cultivation of any part of a country occupied by savage tribes, no part is cultivated. Were any one to cultivate a patch of such land, he might have his right to the crop disputed, and lose the benefit of his labour. It is impossible for men to exert industry under such circumstances. With a common, again, no one has so great an interest as to induce him to keep the ground in order; hence such pieces of ground generally become nearly waste and useless. The principle may be still more familiarly illustrated:—Suppose a cherry-tree growing in a hedge-row, and no one's property in particular. No person will be at any pains to protect the young fruit of that tree from the birds by means of network; and every cherry which the birds spare will be taken before it is ripe by idle children. There will be no public benefit of any kind from such a cherry-tree. But suppose the tree to become somebody's property. It will then be

cared for and protected; the fruit will be allowed to ripen, and become in due time a source of enjoyment as far as it will go.

It is not enough that property be divided: the right of property must also be *protected*. By the right of property, we mean the right which any man has over what is his own. Thus if a man make a table out of his own materials, he has a right to keep that table, or to sell it, or to use it as he pleases, and no one has a right to take it from him, or molest him in any manner in the use of it. And it is the same thing if he have bought the table, or procured it in any honest manner by exchange.

Now it is the business of every man in the community to see that no man interferes with any other man's property. This is what we call the protection of the right of property. The whole community have committed this power to the legislators, judges, &c. who are called the government. Hence we see that it is the special business of government to protect individuals from violation of the right of property.

The right of property may be violated by *individuals*, as in the cases of robbing, stealing, housebreaking, &c. Were this allowed, no one would labour at all, because no one would labour for the sake of seeing his property plundered and wasted by thieves and robbers. The case is the same when property is plundered and destroyed by mobs. If a man would not labour for the sake of seeing his property destroyed by one robber, he would not labour any the more for the sake of seeing his property destroyed by five hundred robbers.

Hence it is clear that the industry of a country depends very greatly upon the goodness of its laws and the faithful execution of them. If laws allow of violation of property, all men would soon become thieves instead of labourers; and as thieving produces nothing, there would soon be nothing left to steal, and all would starve. And if the laws be not put into execution, there might as well be no laws, and the result would be the same.

But governments themselves sometimes violate the right of property. This is the case when, by the mere will of the government, the property of the individual is taken for any purpose whatsoever. Such is the case in many despotic governments. When this is the case, a people becomes at once spiritless and indolent. Who would labour on the soil through a whole summer, if he knew that he was liable to have his harvest seized in the autumn by a tyrant as soon as it was fit to be gathered? Thus we see that the most fertile regions of the earth, when under such a government, lie almost uncultivated; the inhabitants are few, and these few are extremely poor and spiritless. Hence the importance of a good constitution of government.

But suppose that every man be allowed to gain all that he can, he must also be allowed to *use it as he will*. This is evident, because no man will be industrious to gain property, unless he be allowed to use it for the promotion of his own happiness in such way as he likes best. A man's property are his faculties of body and mind, or his means of industry, and his property or capital. It is necessary, in order to render men industrious, that they be allowed, provided they do it honestly, to use both of these as they choose.

For instance, the labourer should be allowed to work at any trade or as many trades as he pleases, to work in any place that he chooses, and to change his occupation whenever he supposes it can be done for his advantage; he should also not be obliged to change it unless he believe such change will be for his benefit. It is to be supposed that every one understands his own business better than any one else can understand it for him, and therefore to oblige him to make any change contrary to his own wishes will do him an injury, and an injury which is wholly without excuse.

And the same is true of *capital*. Every man that owns anything has a right to use it as he pleases. No one, whether an individual or a government, has any right to direct him in the manner in which he shall employ it. A farmer has a right to raise just such a

crop as he pleases; and a merchant to buy and sell what he chooses, and at such prices as he sees fit. He may ask too much, and may impose upon his neighbours; but if he do so, he will soon punish himself. And though he thus acts ignorantly and wickedly, yet as we cannot control him without interfering with the right of property, it is much better to let him alone, than for the sake of regulating him, to oppress all the other men in the community, and thus, for the sake of punishing one bad man, to injure a hundred good men.

Another condition of society favourable to productiveness, is the intelligence of the people. If they be ignorant, they neither are sensible of the importance of industry, nor know how to exert themselves to the best advantage. It thus becomes of great consequence that all should be, to a certain extent at least, enlightened by knowledge.

#### IL EXCHANGE

We have thus far considered production, and the means by which, with a given amount of labour, production may be increased. But were this all, the happiness of man would be but in a small degree increased. Were a man to make everything for himself, or, what is the same thing, have nothing but what he could make himself, though his labour were ever so productive, he would enjoy but very few comforts. Though a farmer, instead of raising a hundred bushels of wheat, could raise three hundred bushels, yet if he did not need for his own consumption more than a hundred, and could not procure anything else with his additional two hundred, he would be no better off than before, but might as well suffer this additional product to rot upon the ground. His additional labour would bring him no additional advantage, and hence there would be no encouragement to labour. But as soon as he is able to exchange this two hundred bushels more than he can use himself for some other things which he wants, his additional labour brings with it a corresponding reward; and additional productiveness of labour brings with it additional comforts and conveniences. Of so great advantage to mankind is exchange. Hence it will be seen that the prosperity of a country, its wealth and its industry, are very much in proportion to its facilities for exchange. Thus we see that no country can easily become rich without available harbours on its coast, good roads, canals, and railways in its interior; and that its advantages are greatly increased when it is so fortunate as to be penetrated in many directions by navigable rivers. We shall now proceed to consider the nature and principal laws of exchange:—

#### OF THE FACTS IN OUR CONSTITUTION WHICH RENDER EXCHANGE UNIVERSALLY NECESSARY.

1. It is a well-known fact that labour is necessary in order to render anything valuable. Everything valuable around us will, if we reflect, be seen to be the result of the labour of some one. And we have also seen that he who has laboured has, by means of that labour, acquired a right to the value which he has created. By this we mean that he has a right to do with it just what he pleases.

2. It is also the fact, that every man seems disposed to pursue some one kind of occupation in preference to another. One man chooses to be a sailor, another a farmer, another a mechanic, another a manufacturer, and another a merchant. And we also see that these different men seem each one to be the best adapted to that kind of business which each one has chosen. And we know that, by the principles of division of labour, there will be a much larger amount of product created when every individual has a separate employment, than when every man is obliged to distribute his time and energies between a dozen employments.

3. But while every man is thus intended to labour at one particular employment, and to produce one particular thing, every man needs for his comfort and con-

venience a thousand things. Now, as he labours to produce only one of these thousand things, he must procure all the rest by exchange; hence, in order to gratify his desires, he must make nine hundred and ninety-nine exchanges. By so doing he is able by labouring to produce one kind of value, and then by exchange to supply himself with every kind of value that he wishes. In this manner men are rendered happier, inasmuch as every one is enabled to pursue the occupation that he likes best, and at the same time to procure whatever he needs for his happiness. And moreover, as by this mode labour is much more productive, every one procures a much larger quantity of what he desires by the same amount of labour.

We thus see that in order to secure our physical happiness, there is really as great a necessity for exchange as there is for production. This rule applies equally well to nations as to individuals. No nation is able to raise within itself one-half of the productions necessary to its convenience. It may have, however, peculiar advantages for producing some one or two articles of general necessity. These are commonly called its 'staples.' Now it is for the advantage of a nation, as well as of an individual, to devote itself to the production of that which it can produce in the greatest abundance and with the greatest ease, and then to procure by exchange with other countries those articles which it needs, but which they produce with greater ease and in greater abundance. The benefits in this case are of the same nature as in the other. Each nation labours in that department of production which it chooses; and at the same time, by so doing, it is enabled in greater abundance to avail itself of the productions of every other country.

Since there is so great an amount of exchange which must of necessity be made, it is evident, from what we have said on the subject of division of labour, that there will be a great saving of labour—that is, the labour of the whole society will be much more productive, if some portion of the community devote itself to the business of conducting exchanges. Thus if there were in a given town a hundred families engaged in the various kinds of production, and requiring for their own convenience a great many exchanges with each other, it would be a great saving of time and labour if some individuals should give up all other business, and employ themselves entirely in the business of exchanging. They would then receive the various products of the different producers, keep them on hand, and offer them in barter to such as wanted them, and they would carry the productions of the town to a city, and exchange them for what might be wanted by their friends at home. It may be easily seen that such an arrangement would be a great convenience.

Such arrangements are always made wherever men are industrious and frugal, and hence have anything to exchange. The men who thus employ themselves in exchanges are called merchants, and are usually spoken of in the language of commerce as retail and wholesale merchants:—

*Retail merchants* purchase in large quantities of importers or wholesale merchants, and sell again to consumers in such quantities as they may desire. In doing this they greatly benefit all parties. The wholesale dealer could not afford to break open a barrel of sugar to sell a pound, unless he charged a very high price for his trouble. The consumer could not afford to purchase a bag of coffee, or a barrel of sugar, or a whole piece of broadcloth. And besides, a man is rarely a judge of the goods he wishes to purchase, and it is much better for him to use the skill of a good judge than to attempt to judge for himself.

The *wholesale merchant* imports in large quantities from abroad, or purchases in large quantities from the manufacturer at home, and sells to the retail merchant, who, as we have said, sells to the consumer. The importance of this kind of labour in exchange is as evident as the other. The retail merchant could not import from abroad in so small quantities as he wishes to

purchase, unless with much additional expense. One wholesale merchant could import as much as would supply a large number of retail merchants, and with but very little more labour than would be demanded of every individual who only imported the small quantity which he needed for his own sales.

The interest of the merchant requires that he should buy as cheap as possible, that he may sell as cheap as possible; for the cheaper he sells, the more numerous will be his customers. Hence the wholesale merchant will export what he can export cheapest, will exchange his export where he can do it the most to his advantage—that is, where he can procure what is most wanted at home, and where he can do it at the lowest rates. So the retail merchant knows that the better his goods are, and the cheaper the rate at which he sells them, the greater will be the number of his customers, and the greater the number of exchanges which he will be able to effect within a given time.

Hence we see that the real interest of the merchant and that of the whole community are the same. The retail merchant can become rich in no other way than by purchasing as cheap as he can, that he may be able to sell as cheap as he can; for if he sell dearer than his neighbours, no one will buy of him. And so the wholesale merchant can grow rich in no other way than by sending abroad what is cheapest at home—that is, what is least wanted there, and bringing back what is dearest at home—that is, what is most wanted there. Thus we see that if merchants conduct their business correctly, they cannot grow rich in any other manner than by doing a real service to the community in which they carry on their transactions.

SOME OF THE PRINCIPAL FACTS IN REGARD TO EXCHANGE.

1st, In making exchanges with each other, men proceed upon the principle of exchanging labour for labour. What men can procure without labour, they will give away without demanding labour for it. What they have to labour a day in order to procure, they will not exchange for anything which they could procure by labouring half a day. And thus, in general, when one product costs more than another, it is because it requires either more labour, or more skilful labour, than the other to produce it.

Here, however, we should always bear in mind the nature and effect of accumulated labour. If a man labour six months upon a wind-mill, this wind-mill represents the labour and skill of six months accumulated in one machine. If he use this mill for grinding flour, he is entitled not only to the price of his labour per day, but also to remuneration for the use of his accumulated labour. Now all machinery and erections, all fixed capital of every kind, railways, canals, &c. are so many forms of accumulated labour; and it is manifest that for the use of this labour, as well as for the daily labour by which it is put into operation, the owner is entitled to a fair remuneration. And also it is evident that if capital be left free and unencumbered, this kind of labour will, by competition, be brought to yield, like every other species of capital, no more than its proper and fair recompense.

While this, however, is true in general, it is also true that the exchangeable value of all articles is liable to sudden and limited variations in consequence of the variations of supply and demand. In such cases sometimes an article will bring more, and at other times less, than the cost of the labour necessary to produce it. These, however, never can continue long, and they in the end equalise and compensate for each other; so that they do not at all invalidate the general assertion, that when men exchange, they exchange on the primary principle of labour for labour.

2d, The exchanger, or merchant, confers no new value on a product, he only saves labour and time to the producer. The article which a merchant buys is not changed in any manner by his labour. He who sells penknives, or calicoes, or sugar, or coffee, sells these articles just as he receives them. And so of the ar-

ticles which he purchases to export in payment for them. Nevertheless, he is still performing a service of great advantage to the community. Were the farmer, who wanted a scythe, obliged to carry his wheat to the *scythe manufacturer*, and exchange it himself, his scythe would cost ten times what it costs at present. The case is still stronger, if he were obliged to go to Sheffield or Manchester to procure the hardware which he wanted. Hence although the merchant does not himself add any new value to his wares, yet by reducing the cost at which they must otherwise necessarily be procured, he does as great service to the community as those who actually produce. He enables other persons to produce twice as much as they would be able to produce otherwise, and this is the same thing to the community as though he were the producer himself.

3d, Hence it will be seen that the more rapidly exchanges are made, the better it will be for the merchant and for the community. It will be the better for the *merchant*, because he thus, with the same capital, makes a greater number of exchanges in a given time, and thus makes a greater annual profit, while he charges a smaller advance upon each exchange. Hence it is better for the *community*, because the less the advance which he charges, the less is the price which they are obliged to pay for what they purchase. Thus we see that, in prosperous times, trade is brisk; that is, exchanges are made rapidly, and with the greatest advantage to both parties.

4th, There are three circumstances on which the frequency and infrequency of exchanges depend:—

1. *The Intelligence of a People.*—Every one has a desire for the various means of happiness which God has spread around him, if he know what they are, and how he shall obtain them. Every one who has read the voyages of the early navigators, must have seen how eager the inhabitants of the newly-discovered islands were to exchange, as soon as they beheld the various instruments, and tools, and ornaments of civilised men. And thus we see that newspapers, travelling, and all the ordinary means by which information is circulated, have a great effect in increasing the desire of men to improve their condition by means of exchange; and that they are thus induced to labour more industriously, in order to procure something to offer in exchange for what they want.

2. *Productiveness of Industry.*—It is not enough that a man be desirous to exchange; he cannot gratify that desire unless he be able to offer something to the other party which will be accepted in barter. If I desire a barrel of flour ever so much, I can never obtain it unless I am able to offer to the flour merchant something which he will accept in exchange for his flour. Thus every one knows that a rich man is able to make a great many more exchanges in a year than a poor man. A labourer who earns high wages can make many more exchanges in a year than a labourer who earns but low wages. A farmer buys many more articles of comfort—that is, makes many more exchanges—in a productive than in an unproductive season. And thus in general every one must observe that a wealthy country makes more exchanges, both internal and external, than a poor country; a prosperous than a declining country; and the same country in a period of successful than in a period of unsuccessful industry.

3. *Moral Character.*—Men do not always exchange their products at the same instant, but one or the other frequently waits some time for the return which he is to receive in exchange for his product. This gives rise to a liability to dishonesty. And besides, when men are dishonest, they will frequently cheat each other either in the quantity or in the quality of the article which they offer in exchange. Now where these liabilities exist, they will greatly lessen the number of exchanges. No one who can help it will have any dealings with a rogue. Hence when men are disposed to be rogues, exchanges will diminish. Laws are made to oblige rogues to act like honest men; hence when laws are just, and are well administered, exchanges

will be more frequent than when they are unjust, partial, and unfairly administered. But every one must see that on the moral character of a people, not only their personal honesty, but also the soundness and efficiency of their laws, depends. Hence we observe that morality, using this word in its most extended sense, is of the greatest importance, not only to success in production, but also to success in exchanges.

And the same principles apply to our exchanges with foreigners. If we treat them justly and kindly, and allow them all reasonable means for enforcing their rights, they will come and exchange their products for ours, in preference to going to another country where they would be less favourably treated. Thus we shall be able to procure, on the most favourable terms, whatever we need from other nations, and in this manner reap the richest reward for our industry and moral character. A selfish, exclusive policy is as self-destructive a policy for nations as it is for individuals.

And if this be the case, we shall easily determine what are the causes which naturally diminish the frequency of exchanges, or which produce stagnation and derangement in business.

If the *desire* for any particular product diminish, the *demand* for it will diminish; hence those who produce it, and those who keep it for sale, will be unable to sell it. Thus the changes in fashion frequently destroy in a short time the entire demand for an article which a year ago was in vogue. Or the diminution of the intelligence of a country will in due time produce the same effect on exchanges generally.

The diminution of production during a single year will produce the same effect for that year; and oppression, heavy taxation, or anything which interferes with production, or diminishes the productiveness of human industry, will accomplish the same result permanently. And hence it is that as a nation becomes vicious, unjust, or oppressive, such moral deterioration must produce a diminution of exchanges, in the same manner as it interrupts all other kinds of industry. And thus success in exchange, as well as success in production, depends in a great measure upon the intellectual and moral character of a people.

From what has been said, it will be easy to perceive in what manner a government can best *promote* the business of exchange. It is by promoting the intelligence and virtue of a people—by giving every facility for the increase of the productiveness of industry—by encouraging, in every suitable manner, the establishment of roads, canals, railways, and means of internal communication—by rendering its harbours and coasts as easy of access as possible—and by giving to foreigners every reasonable facility for the transaction of their business when they come amongst us. In other words, by conducting its business, both internal and external, upon principles of the most perfect fairness and freedom.

And we see also what measures are in their nature most likely to *diminish* the number of exchanges. Such are duties on imports, or, in other words, adding to the price of every foreign commodity offered in exchange, obstructing the means of intelligence, refusing the necessary facilities for constructing means of internal communication, imposing unnecessary disabilities upon foreigners, neglecting the condition of harbours and coasts, and in general any course of measures by which the article offered in exchange is rendered more expensive, or by which the person who comes among us for the purposes of exchange is denied any reasonable means for seeking his own interest or happiness.

[Of exchange by means of money, metallic and paper, a full exposition is presented in the following sheet entitled COMMERCE—MONEY—BANKS.]

### III. DISTRIBUTION.

We have thus far considered the mode in which wealth is, in the first instance, produced, and in which, in the second instance, the producers are best enabled to exchange it with each other.

It is, however, commonly the case that an article of production is not the result of the labour of one man alone, but of several men united. Thus several men successively unite in producing a barrel of flour. One owns the land on which it is grown, another sows the seed, another reaps the harvest, another owns the mill in which it is ground, another manages the mill for the owner, another makes the barrel in which it is contained, another transports it to market, and another sells it to the consumer. Now every one of these must be paid out of the barrel of flour when it is purchased by the consumer; that is, the price of the flour must be so *distributed* among them all, that each one has his just share of the proceeds. The principles on which this is to be done are considered by political economists under the head of *DISTRIBUTION*.

As all value is the result of capital and industry, it is manifest that we shall comprehend the whole subject, if we treat of *Wages*, or the price of labour, and *Interest*, or the price of capital. Inasmuch, however, as *Capital in Land* is in some respects peculiar, we shall consider it separately under the head of *Rent*, or the price of land.

#### WAGES, OR THE PRICE OF LABOUR.

Of the General Principles by which Wages, or the Exchangeable Value of Labour, is Regulated.

We have already seen that exchangeable value is the cost of anything, influenced moreover by the effect of supply and demand. We shall therefore consider, *first*, The cost of labour; and *secondly*, The effect of supply and demand upon it:—

##### I. Of the Cost of Labour.

*Of Simple Labour.*—By simple labour we mean that labour which may be performed by any healthy person without any, or with very trifling, previous education.

1. But it is evident that no person can continue in health without food, clothing, and shelter. We cannot, therefore, procure the labour of any living thing without furnishing those necessaries which are required for the continuance of existence. This is the first thing which enters into the cost of labour.

2. But besides this, human beings are not qualified to labour until they have attained several years of age. During the period of infancy, they must be supported by the labour of others. Were they not so supported, the whole race of man would in a few years perish. The cost of labour must therefore be sufficient to sustain not merely the parents, but also the children. And yet more, men live frequently after they have ceased to be capable of labour. The old must be supported, or they will perish. Hence the wages of labour should be enough to enable the labourer to lay up something to support him in his old age, or else the wages of his children should be sufficient to maintain him after he has become unable to maintain himself.

3. While, however, this is the fact, yet it may be observed that the cost of labour, or the remuneration necessary to accomplish these purposes, will vary in different climates. In warm climates, where vegetable food is principally used, and where very little expenditure is required either for fuel, clothing, or shelter, wages would naturally be lower than in cold climates, where the expenditures must of necessity be so much greater. This is, however, equalised by the fact, that warm climates enervate the system and relax the physical energies; so that, while you pay a very small sum for a day's work, you receive a corresponding small amount of labour in return.

Such is the natural cost of simple labour, and it will be generally found that by this rule that cost is practically adjusted. Whatever may be the condition of the country, the lowest class of labourers earns but simply sufficient to procure the ordinary necessaries of life for the parents and the children.

*Of Educated Labour.*—But for most of the occupations of life some sort of education is required. No man can

be a carpenter, or a blacksmith, or a jeweller, or a physician, or a lawyer, or a clergyman, without being educated for the particular calling which he intends to pursue. Now this education is expensive. It costs both time and money. If a man wish to practise a trade or a profession, he must spend several years in preparation or apprenticeship. During the whole of this time he receives no wages, and frequently is obliged to pay for tuition. When he has acquired the necessary skill, he is able to perform more valuable labour than before, and he is entitled to a higher compensation. This compensation would naturally reasonably be adjusted by a consideration of the time and capital which he has expended in his education. The longer the time, and the greater the expense of his training, the higher ought to be his wages. It is evident that the wages of such trained labour must be always greater than those of simple labour, otherwise it will not be produced. No man will spend money in educating his son for a profession which will yield him no higher wages than he could earn without any education.

Such are the principles by which the cost of labour is adjusted. Wages must always be sufficient to support the labourer, and to remunerate him for the expense which must be incurred in acquiring the skill necessary to the practice of his profession.

## II. Of the Demand for Labour.

We shall consider this under two divisions—*first*, The demand for simple labour; and *secondly*, The demand for educated labour.

1. The demand for simple labour, or that which is indispensable to the production of the ordinary necessities of life, is incessant and universal. Every man requires, either indirectly or directly, the labour which is employed in producing the ordinary articles of consumption for food, clothing, and shelter.

But in order to render this labour available, it must be united with capital. Neither labour nor capital can produce anything alone. Hence he who possesses capital is always desirous to unite it with labour, and he who is able to labour is always desirous to unite that labour with capital. And it is evident that the larger the amount of capital which a man possesses, the greater will be the amount of labour which he will wish to procure. He who cultivates five hundred acres of land will require a larger number of workmen than he who cultivates but fifty acres. The iron founder who wishes to manufacture five hundred tons of iron will require a greater number of workmen than he who wishes to manufacture but fifty tons. And hence in general we see that the greater the amount of capital, the greater will be the number of labourers required—that is, the greater will be the demand for labour.

If the capital of a country be too great for the number of labourers, there will be a competition between capitalists for labour. They will overbid each other, and thus the price of labour will rise. Those of the first class will be insufficient to supply the demand for labourers of this class, and a number of labourers must therefore be taken from the second class. And thus in succession every class of labourers will be raised one grade. The price of labour will thus be raised throughout the whole community, the condition of the people will be meliorated, a smaller proportion of children will die, and a larger number of labourers will be reared. If the addition from this natural source do not supply the deficiency, labourers will then immigrate from less favoured countries, where the proportion of capital to labour is less.

On the contrary, where the proportion of capital to labour is small, there will be a larger number of persons desirous of labour than can find employment. In this case there will be a competition among labourers for work. They will underbid each other, and thus the price of labour will fall. The case mentioned in the last paragraph will then be reversed; the condition of all the labourers will be rendered worse, and many will either emigrate or starve. Many children and weak and sickly persons will die of the diseases consequent

upon insufficient nourishment and exposure. In this manner the number of human beings will be reduced until the supply of labour is adjusted to the amount of capital, and then the price of labour or wages will rise again. Hence we see that, in order to secure the prosperity of a country, it is necessary that its capital should increase with its population. No matter what may be the present condition of a people, if population increases faster than capital, or if capital remain stationary, or specially if it be diminishing, there must soon arrive a season of great distress among the labouring-classes. There will then be more labourers than can find sustaining employment.

Hence we see the great importance of both individual and national frugality. He who squanders away property in useless expenditure, is annihilating the very means by which the honest labourer might earn his subsistence. Thus also of nations. The government that wastes property in wars, or in any other form of unprofitable consumption, is diminishing the capital of the country, and scattering the resources which the toils of the people have accumulated. Every shilling thus spent is the destruction of so much of the means by which the labourers of the country are to be sustained. Suppose a nation be worth a hundred millions of capital, and that the use of all this capital be necessary in order to furnish employment and the means of subsistence to its population. If it spend ten millions in war, that part of its population which was sustained by the use of that ten millions must be unemployed. Or if this portion be not immediately thrown out of employment, and the injury be averaged, the price of wages for the whole will be reduced to the amount of this difference; every one will be worse off, and the lowest will be destitute, and will starve.

*Of the Demand for Educated Labour.*—This is substantially dependent upon the same principles. A community needs the services of lawyers, physicians, clergymen, judges, and men of science. Hence there will be a demand for these services. If there be a greater number of educated labourers than is required, the price of the wages of such labourers will fall. Under contrary circumstances it will rise. When the price of educated labour falls so low as not to remunerate the labourer for his skill and education, the supply will be reduced by the fact, that men will turn their attention to some other pursuit.

The demand for these different kinds of labour varies with the condition of society. The rich and luxurious have greater demand for medical aid than the poor and abstemious. The progress of society renders titles to land more intricate, and exposes men to greater danger from fraud. Hence the greater need of the services of those who have devoted themselves to the study of the laws, and who are therefore qualified to instruct us how we may avail ourselves of the benefit of law.

III. We next proceed to consider the *supply* of labour, both simple and educated.

The amount of labour in any country depends upon the number of healthy human beings inhabiting it. Hence the supply of labour will depend chiefly upon those conditions by which the increase or the continuance of human life is affected. Of these conditions the most important are the following:—

1. The means of living which may be commanded by the labourer. Where wages are low, and the means of living are with difficulty procured by the labouring-classes, the increase of population will be small, nay, population may become stationary, or it may even decrease. When a family, for instance, with its utmost labour, in health, can barely provide the means of subsistence, they must all suffer greatly in sickness. In such cases, parents or children very frequently die from the want of common conveniences or attentions. And as sickness is a calamity common to all men, under such circumstances large numbers of the poor must perish. For this reason epidemic diseases, especially those of children, are found to be much more fatal among the poor than among the rich. In countries

where the wages of the poor are very low, it is not uncommon to find parents who have had large families almost childless. On the contrary, just in proportion as the labouring-classes are enabled to provide themselves with all the conveniences of living, will the number of children who are reared be increased.\*

And besides, labourers will readily emigrate from other less favoured countries to that in which the condition of the labouring-classes is happy and prosperous. In this manner population will always flow from old to new countries, and from regions where labour is poorly repaid to those in which it receives a more generous remuneration. Both of these circumstances tend at present to increase the population of the United States. There the wages of labour are high, and the means of living abundant. Those who are willing to labour can always command the necessaries, and frequently the conveniences of life, both for themselves and for their families. Hence a much smaller proportion of children die there than in older countries, and of course the population is much more rapidly augmented. And from the same cause—namely, the high price of labour—there is annually a prodigious amount of emigration thither from the older countries of Europe.

2. The next condition necessary to the rapid increase of population, is the moral condition of a people. Vice is always awfully expensive, and terribly desolating to human life. It matters not how great be the wages of the labourer; if those wages be spent in intemperance and profligacy, his family will suffer or starve. In some countries, such as the United States, almost all the suffering of children is the consequence of the vice of one or of both of their parents.

On these two circumstances, therefore—the wages of the labourer, and his own personal moral habits—does the increase of population principally depend. And as we have before stated, the supply of labourers is as the increase of population.

The same principles in the main govern the supply of educated labour. If the wages of such labour are sufficient to pay for the expenditure of time and capital necessary to the acquisition of the education, such labour will be produced—that is, men will turn their time and talents in this direction. On the contrary, when the remuneration of such labour is inadequate, men will not prepare themselves to perform it, and those already educated will devote themselves to some other occupation. The supply will thus be reduced so as to correspond with the demand.

**Of Circumstances which Affect the Rate of Wages in Particular Instances.**

We have seen that a given amount of capital is necessary in order to furnish employment for an individual labourer. Hence any given amount of capital directed to any one business, will only furnish employment for a corresponding number of labourers. And moreover, if any portion of the capital now employed in any one kind of business be withdrawn and devoted to any other kind of business, there will follow a change in the rate of wages in that employment. The wages in the business from which capital is withdrawn will fall; those in the business to which capital is directed will rise. Such is the result of all legislative enactments which affect the employment of capital.

But besides this more general cause, the price of labour in the several professions is affected by various special circumstances. For instance—

1. By the ease or difficulty, the pleasure or pain, &c. of the employment, and by the estimation in which it is held by the community.

When any trade is in its nature unpleasant, men do

\* It has latterly been surmised, with considerable probability, that the sinking of a population below a certain point in comfort, introduces conditions which tend to its increase; but the increase produced in these circumstances does not operate as a healthy increase would do, the people being then ill-cared for, ill-reared, ill-educated, and perhaps also dangerous, and therefore injurious to the development of the powers of capital.—Ed.

not like to practise it. Hence when we wish to employ them, we are obliged to overcome their reluctance by higher wages. When the performance of the labour is pleasant, many persons are willing to engage in it, and hence the supply being greater than the demand, the price of the labour falls accordingly.

2. By the skill required in performing the operation.

This results from two causes. First, the greater the skill required, the smaller will be the number able to perform the operation. Thus the supply will be small. And secondly, the longer will be the time spent in learning to perform it, and hence the greater wages will the labourer be entitled to receive.

3. The confidence reposed.

In many employments much reliance must be placed in the moral character, the courage, the discretion, the talent, and forethought of the agent. But inasmuch as these qualifications are not frequently found united in the same individual, the number of suitable candidates for such employments is small. Hence as the supply is commonly less than the demand, the wages in such employments are high. And inasmuch as those who have a large amount of capital at stake, find it for their interest to procure such labourers at any price, the wages of such persons will always be much higher than in cases when no such confidence is of necessity reposed.

4. Constancy or inconstancy of employment.

Some kinds of labour furnish incessant employment; others furnish employment only at intervals. Yet in the one case, as well as in the other, division of labour requires that the labourer devote his whole time to his business. Hence in the latter case it is reasonable that, for the performance of a particular operation, he should receive a larger remuneration than in the former. We pay more for riding a mile in a hackney-coach than for riding a mile in a stage-coach, because the employment in the one case is constant, and in the other inconstant. A large portion of the time of the driver of a hackney-coach is consumed in waiting in readiness for passengers. For this time we must pay our portion whenever we employ him.

**OF THE PRICE OF MONEY.**

**Why we pay Interest for the use of Money.**

The leading question which arrests our attention in the consideration of this subject is the following:—Why should the use of money have any price at all? As I return to a man the same value which I borrow of him, why should I pay him anything for having kept it during the interval? This question we shall in the first place attempt to answer.

Every man who labours at any regular employment possesses two qualities which render his services of value—these are *strength* and *skill*. The former enables him to execute simple labour, or labour of the cheapest kind; the latter, when united with the former, enables him to execute educated or higher-priced labour. But in order to perform the latter, he requires tools and materials—that is, capital. Without these he could perform only simple labour. Of what use would be the skill of the blacksmith without a forge and iron? or that of the carpenter without tools and wood? or that of the spinner without a spinning-jenny and raw cotton? Without these they would be all reduced to the necessity of that labour which could be performed with their naked hands.

Suppose now that I am a blacksmith, and own a forge, tools, and iron, with which I am daily employed, and thus earn the wages both of labour and skill: were I to lend them to another man for a week, and carry a hod during the meantime instead of working at my trade, and thus lose the profit of my *skill*, he who thus borrows my forge, tools, and iron should surely remunerate me for the use of them. Suppose he borrow them for a year, he should pay me for the same reason. And if I have the money with which he can purchase them for himself, and I lend it to him,

could have made profitable to myself.

And here we may remark, in general, that when we speak of the loan of money, it is in reality not money, but other capital that is wanted, and for which we pay interest. Were a tradesman to keep the money which he borrows locked up in his drawer, it would be worth nothing to him. It can be only of use when it is exchanged for something else, which, being united with labour, will yield a profit. The fact is, that every one, as soon as he procures money, exchanges it for tools, or materials, or merchandise. Every one sees that these ought to pay interest, because they are the means of accumulation. Just as much should the money pay interest which is exchanged for them, and for which the owner of the money would have exchanged them, if he had not lent it to another.

Now it very frequently happens that the ability to labour is possessed by men who have no capital upon which to employ it. And on the other hand, capital is frequently possessed by individuals who have neither the skill nor the ability to labour. In such a case it is manifestly for the interest of both parties to form a copartnership, the one party furnishing the labour and skill, and the other furnishing the capital. By this means both parties are benefited. The labourer earns the wages of labour and skill instead of those of simple labour; the capitalist derives an income from his property without diminishing it, instead of being obliged to live upon the principal.

Now this takes place in two ways, both the same in principle, although the mode in which the arrangement is made is dissimilar.

The first is the case of wages. Here there is virtually a partnership formed between the capitalist and the labourer. The one furnishes the tools and the material, and takes all the risks of the operation, and divides with the labourer the profits, which he pays in the form of wages. These are generally agreed upon at the commencement between the parties, and are the same whether the operation be profitable or unprofitable. This, however, is not always the case. In the whale-fishery, the crew of a vessel receive a *pro rata* proportion of the profits in the place of regular wages, and of course their remuneration is greater or less according to the success of the voyage.

The second case is that in which the labourer assumes the risk, receives all the profit himself, and borrows his capital from the other, agreeing to pay him at a stated rate for the use of it. This is commonly the case in the borrowing and lending of money. If I purchase a shop and stock it with goods, and employ another person to keep it for me, paying him the customary wages, I act in the first-mentioned manner. If I lend him the money by which he purchases the shop and stock, and he trades on his own risk, paying me interest on the amount borrowed, I act in the second capacity.

It is the latter case that is to be considered in this place. Here the borrower uses the capital of the lender for his own advantage, and that advantage is equal to the difference between simple labour and labour united with skill. Did he not thus employ this capital, the lender would employ it himself. It is therefore just that the borrower of money should pay for the advantage which he gains, and of which he, by thus gaining it, deprives the owner.

Of Various Circumstances which affect the Rate of Interest.

We have thus far endeavoured to show that a price—that is, interest—should justly be paid for the use of capital. But we find that the interest of capital is different in different countries at the same time, and in the same country at different times, and in the same country and at the same time it is different in different kinds of investment. To the circumstances which give rise to these differences let us now attend:—

And here we may remark, in general, that when he can scarcely make 5 per cent. per annum. And it is evident, on the other hand, that the borrower will be willing to pay a higher interest in the former than in the latter case, because he will be able to make a higher profit by the use of it. Hence when land is both cheap and productive, interest will be high, because the investment of capital and labour in land and cultivation will be exceedingly profitable. The same reason operates in other cases.

Whether the productiveness of capital be great or small, supply will affect the rate of interest. When the supply is small, there will be a competition among the borrowers, and the lender will consequently receive the largest possible share of the profits; that is, interest will be high. When capital is abundant, there will be a competition among the lenders: interest will fall; that is, the lender will receive the smallest share of the profits.

Both of these causes tend to produce the high rate of interest so commonly observed in new countries. Land is cheap. It is in its highest state of fertility. All labour bears a very high price, for the results of labour are imperatively demanded; and at the same time capital is scarce, while the demand for it is incessant. As a country grows older, these circumstances change, and the interest of money gradually falls.

II. Secondly, another circumstance affecting the rate of interest is the *risk* of the investment.

When a man parts with his property, and places it in the power of another, there is at least a chance that he shall never see it again. This risk should justly be added to the price which is paid for the use of capital. Thus suppose that the fair compensation for the use of capital in one case were 5 per cent., on the supposition that it was perfectly sure; if, in another case, there were a risk equal to two in a hundred of its being totally lost, this 2 per cent. for the risk should be added to the 5 per cent. for use, and the interest of the latter loan would be justly 7 per cent. So in any other case of hazard.

This risk may depend upon several circumstances, as, for instance—

1. *The Nature of the Investment.*—The risk of loss would be less on money lent for the erection of a stone than of a wooden house, and less on that lent for the erection of a house than for carrying on the manufacture of gunpowder. When the whole security rests upon the capital purchased, it is manifest that the risk would therefore depend greatly on the nature of the material and the casualties to which it was subjected.

2. *The Character of the Borrower.*—Men differ greatly in intellectual and moral character. Some, with honest intentions, fail from want of skill; others, with sufficient skill, fail from want of honest intentions. Just in proportion to the deficiency in either of these respects is the hazard of lending increased. Every one must see that he would be better off to lend to a skilful and honest man at 5 per cent. than to a weak or treacherous man at 10 per cent.

3. The risk depends, again, upon *the character of the government*. When a government has gained the character of stability, and when justice is administered with promptitude and impartiality, so that every man knows that the whole power of society will be exerted for the purpose of enforcing his rights, the risk will be by all these circumstances diminished. When it is otherwise, and when a man knows that the justice of a cause gives no assurance of success, the hazard is increased, and interest will of course rise. This is one of the causes of the high rate of interest during the period of baronial oppression in Europe.

III. Thirdly, interest will vary according to the *convenience or inconvenience of the investment*.

When a man lends his money, he does not know how soon he may want it again, or how long he may wish to continue it in its present mode of investment. He, also, who lends money, always desires the interest to be paid punctually, because it is by means of this punctuality alone that he is able to make his arrangements for the payment of his own debts. Now all these circumstances are taken into account by him who has money to lend. He will lend at a lower rate when he can let his property remain lent as long as he pleases, or recall it when he will, and when the interest is paid punctually, than when he is unable to recall it except at a stated time, and may have it returned to him when it is not convenient, and when he cannot rely with certainty upon the punctual payment of the interest.

These several circumstances, as every one must see, enter justly into every transaction in which money is lent. The first is the difference which arises at different times from the *productiveness* of capital. This varies continually with the fluctuations in the success of business, and many other causes. Secondly, the rate of interest varies with the risk of the investment, this risk being liable to every degree of variation. And thirdly, it varies with the convenience or inconvenience of the investment; and all these may be united favourably in one instance, and unfavourably in another.

Hence arises the impolicy and injustice of establishing a legal rate of interest, to which all loans shall be subjected. It is rendering by law a mode of contract *uniform* which combines within itself more elements of *variation* than almost any other that can be named.

It may be useful, in closing this section, to add a few words respecting the nature of stocks, of which we now hear so much in conversation, and see so much in the daily papers:—

Suppose a bank is to be established, a railway or any other public work to be constructed. The sum which is to be invested is divided into portions or *shares* of a given amount; say, for instance, of a hundred pounds each. Whoever wishes to engage in the undertaking subscribes for as many of these shares as he pleases. When he pays the amount at which the share is valued, he receives a certificate of ownership, which entitles him to all the privileges of a stockholder, the principal one of which is, that he is entitled to his portion of whatever profit may arise from the operation. These shares are called *stocks*, and are transferable at any moment; the holder, whoever he may be, receiving the interest, or, as it is called, the *dividend*, at the regular times of payment.

The prices of these stocks rise and fall with the rate of interest which the undertaking pays. If any stock purchased at £100 a share pays the regular rate of interest, it will sell for £100, and then it is said to be *at par*. If it pay twice the regular rate of interest, and is perfectly safe, it will sell for £200 a share, and is then said to be *100 per cent. above par*. If it pay but half the regular rate, it will sell for but £50 a share, and is said to be *50 per cent. below par*. And so of any other instance.

Stocks, like any other investment, vary in price with the degree of risk to which they are subjected. If a stock pay a high dividend, but yet is liable to be entirely consumed by casualties, it will sell for less than another bearing lower interest, but of which the principal is secure. Thus insurance and steamboat stocks, though they pay large dividends, never bring a correspondent price, because of the losses to which they are unavoidably exposed. On the contrary, though an investment at present pays but little, yet is expected at some future time to be very valuable, it will bring a high price, on account of the anticipations which are formed concerning it. It is by such circumstances that the rise and fall of stocks are determined. They are constantly for sale in large cities, and their prices will rise and fall with the hopes and fears, the anticipations and apprehensions, of the buyers and sellers.

## OF THE PRICE OF LAND OR RENT.

We have remarked in the preceding section, that stocks, or any other investments, will bring a price in the market in proportion to the annual interest which may be derived from them. A stock, let it have cost what it may, which produces £6 a year, if 6 per cent. be the regular rate of interest, pays the interest of £100, and it will sell for £100. If it yield £12, it will sell for £200, and so in any other proportion.

Now the same remark applies to the rent of land. If an acre of land, after paying the ordinary expenditure for tillage and carrying the produce to market, will yield £3 profit, it will sell for £50, supposing the regular rate of interest to be at 6 per cent. If the profit that may be derived from it be more, it will sell for more; if less, it will sell for less. And the same principle applies to land, whether it be used for tillage or for dwelling-houses.

Such is the general principle on which the rent of land depends. It is, however, to be remembered that the productiveness of land depends upon two circumstances—*fertility* and *situation*.

1. *Fertility*.—Every one knows that there exists great difference in the fertility of land. With the same cultivation, an acre in some situations will yield twice or three times as large a harvest as an acre in other situations. Some lands require annual manuring, others scarcely ever need to be manured at all. Now inasmuch as from an acre in the one place you can derive three times as much income as from an acre in the other, it is reasonable to suppose that the former would sell for three times as much as the latter.

2. *Situation*.—The products of land, however, are bulky, and it costs a very considerable portion of their exchangeable value to transport them to the market. The price of transportation is always to be deducted from the farmer's profit, and tends by so much to reduce the value of his land. It is on this account that railways, canals, and other means of internal improvement, confer so great a benefit upon a country. They remove the disadvantages of situation by reducing the cost of transportation.

Bearing these principles in mind, it will be easy to perceive in what manner rents will be adjusted in any given country. When a territory is at first settled, the land may be had for nothing: every one being at liberty to choose for himself the most productive lands—that is, the most fertile, and those most favourably situated, will be at first selected. These will bear no price, and will yield no rent, because they may be had for nothing.

When, however, these are all occupied, and others are needed, the land of the next inferior fertility will be put under tillage. As soon as this is done, the first class of lands will yield rent, and will command a price. Suppose lands of the first class to have produced fifty bushels to the acre, and lands of the second class but forty bushels: it will be as cheap for the settler to hire a farm of the first class, at a rent of ten bushels to the acre, as to have a farm of forty bushels to the acre for nothing. When the lands of the second class are all occupied, those of the third class will come into request; and as soon as these are tilled, those of the second class will also command a price, and will produce a rent. At the same time, the price and the rent of lands of the first class will be doubled. In this manner the rise of price and of rent in lands of various grades of fertility will go on increasing, until all the land worthy of cultivation is occupied.

As the common market for agricultural products is on the sea-coast, it might be supposed that the price of land would gradually diminish as you removed into the interior, until its disadvantages of situation reduced its value to nothing. This would be the case were it not for various counteracting circumstances. Among these are the following:—

1. The fertility of land in many instances increases as we retire from the coast. This fertility counterbalances the disadvantages of situation.

3. As a country becomes settled, towns and cities grow up in the interior, and thus bring a market to the farmer. He is as much benefited by the bringing of the market to him, as he would be by the removal of his land to the market.

4. Sometimes a new invention in the arts transforms at once the conditions on which the progress of a country depend. Such was the result of the introduction of steam navigation on the waters of the Mississippi and its tributary streams. This invention opened this whole valley to the Atlantic, and gave to the towns on the banks of the river almost the advantages of a position on the sea-coast.

Besides these general circumstances, on which the commercial value of land depends, some others may be mentioned which are well worthy of notice. Man is endowed with a love for the beautiful, as well as with an intellectual and moral nature, and he very commonly takes these tastes into account in choosing for himself a place of abode. Hence land which is handsomely laid out and tastefully arranged, whether in a village or in the country, will sell for a higher price than that which possesses none of these recommendations. A farm or a dwelling-house, in a well-cultivated neighbourhood, where the people are virtuous and benevolent, will find more purchasers, and of course will sell for a higher price, than one of equal fertility where the inhabitants are ignorant and vicious, quarrelsome and malicious. Hence we see that were men to consult nothing but their own interests, they might very reasonably devote more care than they commonly do to embellishing their grounds, and supplying themselves and their families with the means of intellectual and moral improvement.

Land, however, is not always used for the purposes of agriculture. It is used in cities and towns, merely to afford space for the erection of storehouses and dwellings. In this case of course its fertility is of no consequence, and its only value depends upon its situation. Hence its price will be determined merely by this circumstance. Those portions which afford the greatest facilities for business will command the highest rent; and those which recede from them will command a lower and lower rent, until they have receded so far from the centre of business that the land is only valuable for dwelling-houses. The value of these, again, gradually diminishes until situation is but a small part of the price, and the land may profitably be devoted to gardening. Here the element of fertility again enters into the computation. The land immediately around a large city is thus commonly occupied by those who supply the market with recent vegetables and milk. At a small distance beyond it is devoted to the general purposes of agriculture, and becomes what may be properly denominated the country.

Having thus considered the general principles upon which the distribution of the profits of any undertaking is effected, we shall close this section by an example illustrative of the manner in which these principles operate in an individual instance:—

We will take, for the sake of this illustration, a loaf of bread. A farmer in the West Riding of Yorkshire devotes his land to the raising of wheat. He tills his land, raises his crop, and sells it to the miller. The price which he receives for his crop repays him for the cost of his own labour, the wages and support of his workmen, the cost of manures, the rent of his land, and interest on all the capital which has been invested. If he own the land, he receives the rent himself; if he hire it, he pays it to the landlord. The miller receives the grain, manufactures it into flour, transports it to Hull, and sells it to the flour-merchant. The sum for which he sells it repays him whatever he had paid the farmer, and remunerates him for the cost of making the flour. This must be sufficient to enable him to pay his various workmen, to remunerate him for his

be sufficient to remunerate him for the use of his canal boats, the men and horses that have been employed in navigating them, the expense of tolls, and the interest on all the capital which is employed in the operation. The flour-merchant buys the flour, and keeps it in his storehouse to supply his customers. He is entitled to a sum sufficient to repay him for what he paid the miller, and also to interest on his investment, to remuneration for his labour and skill, and the cost of store-room. The baker purchases the flour of the flour-merchant, and makes it into bread. He charges for his bread sufficient to repay him for what he paid the flour-merchant, and for all his labour and expense in turning the flour into bread. Thus when we purchase a loaf of bread, we pay our proportion of all these several expenses. And these several amounts, in all these instances, are distributed according to the rules which we have laid down. All the labour which has been employed is paid according to its value and skill; and all the capital according to the use and risk to which it had been subjected. The various items of cost, in the production of any article of utility, may be easily analysed in a similar manner.

#### IV. CONSUMPTION.

##### OF THE NATURE AND DESIGN OF CONSUMPTION.

We have thus far endeavoured to show in what manner the various objects for the gratification of desire are produced, in what manner they are exchanged among the producers, and in what manner the share to which each one of the producers is entitled, is distributed to each of them. But we know that all this is done with reference to another object. Everything that is of any value is designed to be used, and after it is thoroughly used, or, in familiar language, *used up*, it is worthless. All these previous operations only prepare the way for *consumption*, and it is consumption that creates the necessity for their being incessantly repeated.

Consumption is the reverse of production. Production is the act by which we confer value. Consumption is the act by which we destroy the value which has been thus conferred. When we speak of the destruction of value, we do not mean that the material itself is destroyed, but only that the form in which a particular value resided has been changed, and that hence that particular kind of value is annihilated. Thus if a load of wood be burned, its power of creating heat is destroyed for ever. If bread be eaten, or thrown into the sea, or burned by accident, or rendered useless by mould, in either case its utility is destroyed, and we say the bread is consumed. And thus we see that it makes no difference as to the fact of consumption, whether any benefit be derived from it or not. In the one case, as well as in the other, the utility is destroyed.

It seems to be a law of nature that we cannot create one value without destroying another. He who chops down a tree and saws it into boards, destroys for ever the value of the tree as a tree. It can never more give shade to the traveller nor gratify the taste of the tourist. He who butchers an ox for beef, destroys for ever the utility of the animal as a beast of draught. If we eat an apple, we annihilate for ever the quality in the apple of giving pleasure to any other being. And thus, in general, consumption is a sort of exchange, in which we surrender one value for the sake either of creating another value, or else for the sake of gratifying some desire which we consider of more importance than the existence of the value which we annihilate.

1. Consumption is either of *labour* or of *capital*. If I purchase five dollars' worth of mahogany, and pay a mechanic ten dollars for his *labour* in making it into a table, I have consumed five dollars' worth of capital and ten dollars' worth of labour. If I have made it myself, instead of employing another, I have consumed the same amount of value in my own labour. And in-

asmuch as it costs just as much to support a human being whether he labour or whether he remain idle, the spending a day in idleness should always be considered as the consumption of a day's labour. In estimating the benefit of holidays, we should always remember that the time which they occupy is the consumption of so much labour. And the profitability of the consumption is to be estimated by the benefit of the result which is attained.

2. Consumption is either *partial* or *total*. Sometimes after one value has been consumed, another and an important value remains. A pair of India-rubber shoes may be worn out, and be useless as shoes, and yet they may be valuable for the manufacture of India-rubber cloth. A linen garment may be worn out, and its utility as a garment may have been annihilated, and yet it may possess an important value to the papermaker. On the other hand, when we eat a piece of bread, as it has but one value, and that value is destroyed, the consumption is total. When we burn gunpowder in fireworks, and, commonly, when we use property to gratify our appetites, the case is the same. Hence we see the importance of consuming every value of every kind which a substance possesses; and also of consuming nothing for the purposes of gratification, unless for a reasonable and adequate cause.

3. Consumption is either *voluntary* or *involuntary*. It is voluntary when we destroy value by design for the purpose of accomplishing some ulterior result. It is involuntary when it takes place by accident. A pile of wood may be burned in a fireplace for the purpose of warming a parlour; or, on the other hand, it may be set on fire by accident, and totally consumed. In the one case, as in the other, the value is destroyed, the only difference is in the result.

Besides, however, the consumption by accident, a continual consumption is going on by the ordinary agents of nature. If a pile of wood is suffered to remain for a long time exposed to the changes of the weather, it will be rendered utterly worthless. Its value is thus as entirely destroyed as it would have been by fire. If a loaf of bread become mouldy through neglect, its value is as thoroughly consumed as if it had fallen into the fire the moment after it had been baked. Vegetable matter decays—animal matter putrefies—the metals are corroded; and thus consumption is continually going on, by which the values which we create will be destroyed unless we watch over them with perpetual vigilance. Childish, imbecile carelessness is enough to render any man poor without the aid of a single positive vice.

4. Consumption is either *rapid* or *gradual*. The consumption of wood for fuel is rapid. The consumption of the axe with which we chop it, or of the fireplace in which we burn it, is gradual. But the one is going on as certainly as the other; and hence in estimating his expenses, if a man wish to estimate them correctly, the one must be taken into the account as well as the other. If a man build a house and occupy it for ten years, the gradual consumption has materially diminished its value. If now, at the close of this period, he estimate the value of the house at its original cost, he will greatly overrate his property. The same is true of furniture, and of everything else which we use.

It need scarcely be remarked, that the annual consumption of an individual is the total amount of values which he consumes, whether in his business or in his family. Unless his annual production be sufficient to replace the whole of his annual consumption, he will run in debt. By as much as his annual production exceeds his annual consumption, he will be growing richer. Hence the object of every thrifty man is to render this excess as great as possible.

#### II. Of the Design of Consumption.

The design of consumption is easily seen. Inasmuch as consumption is the destruction of some value, it is of the nature of an infelicity. We never therefore consume, but with the expectation of procuring some greater good than that which we annihilate. This good

may be of two kinds: First, we consume one value for the sake of procuring another and better value; or, secondly, we consume a value for the sake of gratifying some appetite or desire—that is, for the sake of increasing our own personal happiness.

#### 1. Consumption for the Sake of the Increase of Value.

—In this manner the farmer consumes seed, manures, labour, and tools, that he may thus be enabled to produce a harvest. The manufacturer consumes raw cotton, labour, machinery, &c. in order to produce cloth. The mantua-maker consumes calico, thread, needles, and labour, in order to produce a new dress. And thus, in all the various occupations of men, materials of every kind and labour are consumed for the sake of creating some article of use, or convenience, or luxury.

2. *Consumption for the Sake of the Gratification of Desire.*—Some of our desires have respect to our life, and health, and comfort. Such are the desire for food, clothing, shelter, and the various conveniences by which the heat of summer and the cold of winter may be modified. Others are merely for the gratification of the senses, without any regard to the benefit which we derive beyond that of simple sensual pleasure. Such are the desires for the luxuries of the table, of dress, equipage, and for those modes of living which are demanded by fashion. Some of our desires are gratified by intellectual pleasures, and others by the pleasure of doing good. It is not necessary that I should enumerate all the various modes of expenditure. In general they consume the value which they appropriate, and all that remains is the gratification which they produce.

#### OF THE DIFFERENT KINDS OF CONSUMPTION.

Consumption is of two kinds—*individual* and *national*. Individual consumption is of two kinds—first, for the sake of *reproduction*; and secondly, for *gratification*.

#### Of Individual Consumption for the Sake of Reproduction.

The design of the consumer in this case is the reproduction of capital, in some form different from that in which the capital is consumed. He would gladly produce without consumption were it possible. But to do so is contrary to the law of his being. Consumption is necessary; but if a man be wise, he will consume as little as possible. Production is his remuneration, and if he be wise, he will render this as great as possible. His whole gain is the amount by which his production exceeds his consumption. The greater this excess, the greater will be his profit. The rule by which he should therefore be governed, is to create as large a product as possible by the consumption of as small a value as possible.

The consumption of a producer is of two kinds—of capital and of labour.

*Of Consumption of Capital.*—The principles which should govern us here are, I suppose, the following:—

1. The consumption of capital should be as small in amount as is consistent with the creation of the desired product. A shoemaker who habitually cuts up a side of leather so carelessly that leather sufficient for one pair of shoes is wasted, will never grow rich. The farmer who sows two bushels of seed when one would have answered as well, loses the half of his seed. In China, sowing is always done by drilling instead of broadcast. It has been computed that by this method as much grain is saved as would feed the whole population of Great Britain. The useless expenditure of fuel in Britain is enormous. It is supposed that not more than one-tenth of the heat of the fuel employed is rendered available in a common fireplace.

2. Capital of no greater value than is necessary should be employed to create the desired product. Thus it is for the interest of every producer to ascertain in what manner he may be able to accomplish his purpose, by the consumption of the least valuable materials. The merchant inquires before he imports a product from a foreign country, with what export he can procure it at the cheapest rate. So the manufacturer, if he be wise, will keep himself informed of the progress of sciences

realised by the discovery of a cheaper dye-stuff, or the substitution of a single cheaper material in the place of that ordinarily in use.

3. *Every utility* possessed by the material consumed should be rendered *in the best manner available*. Thus in an oil-mill the flax-seed from which linseed oil has been expressed is a valuable food for cattle. After the brewer has extracted the saccharine matter from barley, the grains, as they are called, are valuable for the same purpose. The tan bark, after the tanning matter has been extracted, is valuable for fuel. This economy of materials is very well illustrated in the manufacture of combs. In a well-conducted establishment of this kind, every part of the horn, the core, the body, the tip, the shavings, the fat, and the mucilage, are all turned to some available purpose.

Nor is this all. The values which are consumed should be *consumed to the very last*. Thus in the working of a steam-engine it is necessary to evolve a great amount of caloric, and this is the most expensive part of the process. Now economy demands that this caloric should be produced at the least possible expense, and that having been produced, it should be used for every purpose that it can be made to serve. But every one must have perceived, by the flame which escapes from the chimney of a furnace, that a very large portion of the caloric evolved is absolutely wasted. A very great economical improvement has of late been made in some of the iron-works in Great Britain. This caloric, which was formerly wasted, is used to heat the air which is blown into the furnace. By this expedient a very great saving of fuel is accomplished.

*Consumption of Labour.*—As labour is expensive in the same manner as capital, economy teaches us to consume precisely as much of it as is necessary to accomplish our purpose in the best possible manner.

1. We should employ no *more* labour than is necessary. Too many labourers will always encourage each other in idleness. When there is one man at leisure to tell stories, the time of several others must be consumed in listening to them.

2. We should employ no *less* labour than is necessary. When, from want of a sufficient number of labourers, one labourer is obliged to perform several kinds of work, we lose the advantage of division of labour, and also expose ourselves to all the inconveniences of confusion and disorder.

3. We should employ labour of no *higher price* than is necessary. In any extensive operation, it will be seen upon reflection that some parts of the process require more skill and attention than others. Some will require labour worth five or ten shillings a day, and others labour worth not more than eightpence or one shilling a day. It is of great importance in any large establishment so to arrange the labourers that no workman shall be employed at a higher price than the labour which he performs is actually worth. It is, however, to be remarked that an error may exist of the opposite kind. It is as bad economy to employ too cheap as too dear labour. In the one case we lose by paying too high a price for labour, in the other by that destruction of materials which always results from the want of skill in a labourer.

4. The labour which we have paid for should *all be performed*. Time is money, to him at least who pays money for it. If it be wasted, his money is thrown away; and by throwing away money no one ever became rich.

In order to secure this result, several things must, however, be attended to. The most important of these is, that he who employs labourers should in person superintend his own affairs. No one will take as much interest in our own concerns as ourselves. When this cannot be done, the establishment should be so arranged as to insure full and vigilant superintendence over every part, and under such responsibilities as will

#### Consumption for Gratification.

Consumption may be conducted upon economical principles or the reverse. It is clearly the interest of every individual that he should not consume his capital by expenditure upon objects which are to yield him no pleasure or profit of any kind; that everything he purchases should be consumed as thoroughly as possible, and not in any respect wasted. In this way no labour is lost. It is the same with national consumption or expenditure. When the public money is spent upon war, upon idle functionaries or sinecurists, or upon any kind of public work which is not to be either directly or indirectly useful, the labour which produced that money is lost, or has gone in vain. It is nothing in such cases to say that money has been circulated, that employment has been given, and so forth. Men do not absolutely need to be kept working in any particular way, and every idle consumer of others' goods than his own is a source of loss to the community. The labour could have been applied otherwise, and to a useful instead of a useless end. 'There is one duty,' says a recent writer, 'very often ostentatiously professed by the richer to the working and trading classes, from which political economists would readily grant them an exemption—the *spending of money for the good of trade*. People have been known to claim credit for this amiable motive not only when pomp and luxury are in reality the exciting causes of their purchases, but even when they fail to pay the price of what they have obtained. The epistolary and miscellaneous literature of the eighteenth century shows that it was sometimes a fixed creed, especially in France, that if the rich did not spend their money on a certain humane and rational scale, the world of tradesmen and labourers must necessarily starve. There is, however, a material difference between what is *spent* in the ordinary acceptation of the term, and what is devoted to productive purposes. In the latter case, whoever receives the money in his hands, be he speculator or workman, must restore something at least equal to it in value, if not more valuable. But spending does not involve this phenomenon in all its grades. Much of the money dispersed around him by an extravagant man is consumed in this or that stage; it very seldom leaves behind it value nearly equal to its amount. . . . If it be right to preach that men should spend money for the good of trade, economy ought to be dumb; it is a paltry household quality that must sink before the philanthropic spirit of animating trade and labour by expenditure. We do not find, however, that any one dares thus to set the two virtues in antagonism against each other. When people speak of encouraging trade, they do so generally, and without reference to any antagonistic principle; and if it were asked whether it were more consistent with duty, both public and private, to spend a sum which would be missed in the household for the benefit of trade, or to retain it for home purposes, it would be difficult to find any one prepared seriously to support the former line of expenditure. In fact, when expenditure for the benefit of trade comes to be considered along with other serious uses of the pecuniary means of a family, they never are deliberately weighed against each other, and the philanthropic motive remains forgotten until the head of the house grows rich.'

\* \* \* We have to acknowledge ourselves indebted for the above sketch of the science of Political Economy to an American writer. It is abridged, with a few alterations, from a small work entitled 'The Elements of Political Economy, by Francis Wayland, D.D., President of Brown University.' Boston, United States, 1837.

## COMMERCE—MONEY—BANKS.

### COMMERCE.
